

Graphical Algebraic Geometry

From Ideals and Varieties to Qudit ZH Completeness

Dichuan (David) Gao

Razin A. Shaikh

Aleks Kissinger

Algebraic geometry has proven useful in several fields in computer science, for example in robotics [1], computer vision [16], and cryptography [12]. Conversely, computational techniques have become influential in algebraic geometry with the advent of computer algebra systems [11]. Of particular interest to us is the use of algebraic geometry in quantum information theory. Algebraic geometry can be used to design classical codes with good asymptotic behavior [22, 4, 15, 26, 27], and these classical AG codes lift to quantum error correction (QEC) codes with equally good properties [2, 21, 13, 18, 17, 24, 25].

The ZH calculus natively supplies classical non-linearity [3]. In the qubit case, this means it supplies all classical boolean functions. In the qudit case, boolean functions become polynomials [23]. Thus there are maps of the form $n \rightarrow \text{ZH} \rightarrow m$ in the ZH calculus, corresponding to componentwise-polynomial functions f of the computational basis. Maps of the form $\text{ZH} \rightarrow \text{ZH}$ are projectors onto the subspace spanned by basis elements that are roots of f . This suggests there is a “classical backbone” of ZH that reasons about affine varieties (solution sets of polynomials) over finite fields.

Classical algebraic structure inherent in quantum calculi is often best characterized by languages of the Graphical Linear Algebra (GLA) family. For example, the CSS codes resulting from classical $\mathbb{F}_2$ -linear codes correspond to the phase-free fragment of the ZX calculus [19], which is picked out by the language of interacting bialgebras [6]. Similarly, the language of interacting Hopf algebras [7, 28] picks out the phase-free fragment of the qudit ZX calculus, which models the linear-relational core of qudit computation. Expanding the algebraic structure from linear to affine algebra, the language of graphical affine algebra [5] picks out the phase-free ZX with a Pauli X gate, which is the affine-relational core of qubit computation [9]. Finally, the language of affine Lagrangian relations picks out the stabilizer fragment of the ZX calculus [10].

The motivating question of this paper is: can we extend GLA in a principled and simple way, to pick out the nonlinear “classical backbone” of the ZH calculus, corresponding to algebraic geometry over finite fields? If so, can we provide a sound and complete set of rewrite rules for that extension?

The answers to both questions turn out to be yes. We construct a diagrammatic language, which we call graphical algebraic geometry (GAG), for a span semantic of affine varieties over finite fields. We prove that it is universal, sound, and complete. Furthermore, we show the intimate connection between GAG and the Galois-Qudit ZH calculus [23, 14]. Using a catalysis-style argument [20], we leverage the completeness of GAG to solve the open problem of finding a complete set of rewrite rules for the Galois-Qudit ZH calculus.

The Polynomial Fragment

Our first step is to construct a PROP with polynomials as its morphisms. Consider the Lawvere theory $\mathbb{L}_{\text{CAlg}_q}$ of commutative algebras over a finite field $\mathbb{F}_q$, which is generated by the following operations:

modulo the usual axioms of commutative algebras, an extract of which is given below:

where I is the ideal generated by $f_1, \dots, f_m$. From these we may build diagrams in “span normal form”

$$\text{Diagram} \xrightarrow{[-]_q} \left(\mathbb{F}_q^m \xleftarrow{f} V(I) \xrightarrow{g} \mathbb{F}_q^{m'} \right) \quad (4)$$

Thus all structured spans are expressible in our graphical language. Conversely, every diagram in $\mathbb{L}_{\text{Span}_q}$ can be rewritten, using our rewrite rules, into span normal form. Completeness, then, is shown by demonstrating that two diagrams in span normal form, if they correspond to isomorphic spans, are rewriteable into each other.

Because $\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)}$ is secretly equivalent to FinSet , so our semantic category is in fact equivalent to ${}_G\text{Span}(\text{FinSet})$, which is in other words the category of $\mathbb{N}$ -entried matrices of q -power dimensions. The xy th entry of a matrix corresponds to the number of points in the variety sitting above points $x \in \mathbb{F}_q^n$ and $y \in \mathbb{F}_q^m$. In this way the language $\mathbb{L}_{\text{Span}_q}$ is also sound, universal, and complete for $\text{Mat}_{\mathbb{N}}$.

In general, the problem of rewriting two diagrams in $\mathbb{L}_{\text{Span}_q}$ is #P-hard. This can be seen by the fact that determining the $\text{Mat}_{\mathbb{N}}$ semantics of no-input-no-output diagrams in $\mathbb{L}_{\text{Span}_q}$, where $q = 2$, is the same as solving a #SAT instance.

Completeness of the Qudit ZH Calculus

Now we show that the qudit ZH calculus [23, 14] can be obtained as a fairly minimal extension of $\mathbb{L}_{\text{Span}_q}$.

Consider the free dagger-PROP $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$ generated by $\mathbb{L}_{\text{Span}_q}$ together with the additional generators: $\textcircled{1} \xrightarrow{[-]_q}$ $\sum_{i \in \mathbb{F}_q} \omega^{\text{tr}(i)} |i\rangle$ and $\boxed{q^{-\frac{1}{2}}} \xrightarrow{[-]_q} q^{-\frac{1}{2}}$, and the additional rules:

$$\begin{aligned} \textcircled{1} \text{---} \textcircled{1} &\stackrel{(\text{Z1-COPY})}{=} \textcircled{1} \text{---} \textcircled{1} \\ \textcircled{1} \text{---} \xi \text{---} \textcircled{1} &\stackrel{(\text{Z1-TRACE})}{=} \textcircled{1} \text{---} \textcircled{1} \\ \textcircled{1} \text{---} \textcircled{1} &\stackrel{(\text{Z1-CHANGE})}{=} \textcircled{1} \text{---} \textcircled{1} \end{aligned} \quad (5)$$

where $\text{tr}(x) = x^p + \dots + x^{p^{p-1}}$ is the field trace polynomial, and ξ is any element of $\mathbb{F}_q$ with $\text{tr}(\xi) = 1$. This extension is sufficient to represent the entirety of the qudit ZH Calculus over $\mathbb{F}_q$. We illustrate by defining a functor $\iota_{\text{ZH}} : \text{ZH} \rightarrow \mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$ on the generators of ZH as follows:

$$\begin{aligned} \text{Z spider} &: n \text{---} \textcircled{1} \text{---} m \mapsto n \text{---} \textcircled{1} \text{---} m \\ \text{H spider} &: n \text{---} \textcircled{1} \text{---} m \mapsto n \text{---} \boxed{q^{-\frac{1}{2}}} \text{---} \textcircled{1} \text{---} m \\ j\text{-state} &: \textcircled{j} \text{---} \mapsto \boxed{q^{-\frac{1}{2}}} \text{---} \textcircled{j} \end{aligned}$$

This functor is consistent with the matrix semantics of ZH and $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$. Thus, we choose $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$ as our axiomatization of ZH. First we show just how minimal an extension $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$ is over $\mathbb{L}_{\text{Span}_q}$:

Proposition. Any diagram D in $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$ factors into a diagram D' containing only the generators of $\mathbb{L}_{\text{Span}_q}$ and a single $\textcircled{1} \text{---}$, up to a finite scalar. In other words, the following rewrite holds in $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$:

$$\textcircled{1} \text{---} \boxed{D} \text{---} \textcircled{1} = \textcircled{1} \text{---} \boxed{D'} \text{---} \textcircled{1} \quad (\otimes k) \quad (6)$$

So a single copy of the state in the fourier basis is sufficient to extend the expressive power of $\mathbb{L}_{\text{Span}_q}$ to cover the entirety of the qudit ZH Calculus. This allows us to apply a catalysis-style argument to obtain, from the completeness of $\mathbb{L}_{\text{Span}_q}$:

Theorem (Completeness of Galois-Qudit ZH). If D_1 and D_2 are diagrams in the Galois-Qudit ZH Calculus over $\mathbb{F}_q$, and $\llbracket D_1 \rrbracket = \llbracket D_2 \rrbracket$, then D_1 can be rewritten into D_2 using the rewrite rules of $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$.

Abstract

We introduce *Graphical Algebraic Geometry* (GAG), a family of diagrammatic languages extending the Graphical Linear Algebra programme. We construct several languages within this family and prove that they are universal and complete for the corresponding (co)span semantics of commutative algebras and affine varieties. This framework provides clear graphical representations of algebraic structures — such as polynomials, ideals, and varieties — enabling intuitive yet rigorous diagrammatic reasoning.

We showcase two practical viewpoints on GAG. First, we show that instances of counting constraint satisfaction problem (#CSP) are recast as rewrite problems of closed diagrams in GAG. This means that deciding rewriteability in GAG is #P-hard, and GAG can be viewed as a complete and compositional rewrite system for networks of polynomial constraints. Second, we characterize the qudit ZH calculus, a diagrammatic language for quantum computation, as an extension of Graphical Algebraic Geometry. This establishes the correspondence that *Graphical Algebraic Geometry is to the ZH calculus what Graphical Linear Algebra is to the ZX calculus*. Using this construction, we show that computing amplitudes in qudit ZH requires only a constant number of queries to a GAG oracle. Finally, using a catalysis-style argument, we leverage the completeness of GAG to solve the open problem of finding a complete set of rewrite rules for the Qudit ZH calculus.

1 Introduction

Algebraic geometry in computer science. Algebraic geometry and commutative algebra have been important influences in several fields in computer science, for example in robotics [1], computer vision [36], and in cryptography [26]. In the converse direction, computational techniques have become influential in algebraic geometry with the advent of computer algebra systems [21].

Of particular interest to us is the use of commutative algebra and geometry in two related areas of research. The first, and perhaps more obvious one, is that of Constraint Satisfaction Problems (CSP) [65]. A CSP instance where constraints are given as polynomials is a problem about an algebraic variety. In particular, in the case where the domain of the CSP is a finite field $\mathbb{F}_q$, the corresponding #CSP instance [41] is to count $\mathbb{F}_q$ -rational points in a variety defined by polynomial constraints — a classical and central problem in 20th century algebraic geometry [38, 68]. More recently, cryptographic

proof systems such as SNARK and STARK have relied on algebraic techniques over finite fields heavily, demonstrating the continuing relevance of this approach [7, 33].

The second area is quantum information theory. It has long been known that algebraic geometry can be used to design classical codes with good asymptotic behavior [8, 32, 35, 40, 61, 66, 67], and that via the CSS or stabilizer constructions these classical AG codes lift to quantum error correction (QEC) codes with equally good properties [2, 27, 42, 43, 56, 57, 63, 64]. Such codes also played a central role in the groundbreaking construction of a magic-state distillation protocol with constant overhead [69]. Aside from error correction, algebraic geometry has also served as a useful language for foundational areas of research such as quantum entanglement and quantum contextuality [16, 25, 29, 53, 58].

Graphical linear algebra and its friends. To systematically understand the role algebraic geometry can play in quantum information theory, we propose that graphical calculi would be useful. Graphical calculi are compositional diagrammatic languages based in category theory, equipped with formal “rewrite rules” with which one can manipulate diagrams rigorously as equational terms. They are usually designed to represent some family of physical phenomena or computational processes. For instance, the ZX calculus and its related calculi have become prominent as languages for representing quantum computational processes [14, 15, 22, 48, 49, 59].

When considering the classical algebraic structure inherent in quantum computing, we often encounter fragments of the quantum calculi that are best characterized by languages in the family called Graphical Linear Algebra (GLA) [10, 12, 70]. Broadly speaking, GLA consists of diagrammatic languages that have denotational semantics built from classical algebraic structure. On the semantic side, the GLA story begins with a category of classical maps: for example, the linear maps between $\mathbb{F}_2$ spaces. It then applies the (co)span or the (co)relation construction to that category to obtain a dagger-category. For example, $\mathbb{F}_2$ linear maps give rise to spans of $\mathbb{F}_2$ linear maps, or to $\mathbb{F}_2$ linear subsets. On the syntactic side, it builds a simple diagrammatic language with generators that have clear semantic interpretations, and rewrite rules that characterize denotational equivalence.

Languages in the graphical linear algebra family are excellent at picking out fragments of quantum computation that correspond to some given notion of a “classical-relational backbone”. For example, the CSS codes resulting from classical $\mathbb{F}_2$ -linear codes correspond to the phase-free fragment of the ZX calculus [46], which is picked out by the language of interacting bialgebras [10], the language that kickstarted the GLA literature. Similarly, the language of interacting Hopf algebras [12, 70] picks out the phase-free fragment of the qudit ZX calculus, which models the linear-relational core of qudit computation. Expanding our algebraic structure from linear to

affine algebra, the language of graphical affine algebra [9] picks out the phase-free ZX with a Pauli X gate, which is the affine-relational core of qubit computation [17]. Finally the language of affine Lagrangian relations picks out the stabilizer fragment of the ZX calculus [19].

Of course, GLA has applications far beyond quantum computing. For instance, the language for linear relations over a field of rational functions $\mathbb{R}(x)$ models signal flow graphs and linear dynamical systems [6, 11, 24], while the language for affine relations models the fundamental structure of concurrency [9]. The strength of GLA lies in its ability to model a remarkably varied set of physical phenomena using the same formal structure.

The need for a graphical nonlinear algebra. However, existing versions of GLA are not yet sufficient to model the fragment of quantum computation with classical algebraic geometry as its “backbone”; nor can they reason about generic constraint satisfaction problems built on polynomial constraints. This is because commutative algebra involves a multiplication operator (an AND gate in the $\mathbb{F}_2$ case), which is essentially nonlinear (and non-affine for that matter). A graphical calculi that models classical algebraic geometry would need to supply such an operator, or equivalently, to supply the Toffoli gate.

In the realm of quantum computing, the ZH calculus [3, 4] or equivalently the ZX& calculus [17, 18] supply such a gate for the $\mathbb{F}_2$ case, and the Galois-qudit ZH calculus [28, 62] serves as the appropriate version in the nonbinary case. The motivating question of this paper is therefore: can we extend GLA in a principled and simple way, to pick out the nonlinear “classical backbone” of the ZH calculus, corresponding to classical algebraic geometry? If so, can we provide a sound and complete set of rewrite rules for that extension?

The solution: GCA and GAG. The answer is yes. However, unlike in the linear case, in which algebra and geometry coincide, we must deal with a gap between commutative algebra and algebraic geometry, which is bridged by a family of theorems known as the Nullstellensatz [30, 37, 39]. Therefore we construct our extension of GLA in two steps.

First, we develop a language $\mathbb{L}_{\text{Cosp}}$, which we call graphical commutative algebra (GCA). Diagrams in $\mathbb{L}_{\text{Cosp}}$ are built from gates corresponding to copying, addition, scaling, multiplication, and the units of these operators — the standard generators featured in the theory of commutative algebras. Diagrams can be reduced to a pseudonormal form that looks like

Denotational semantics are given as structured cospans of commutative algebras. In the pseudonormal form (1), the vertical wires denote a commutative algebra quotiented by the ideal $(g_1, \dots, g_n)$, while f_1 and f_2 denote two algebra morphisms pointing into it. This captures the nonlinear *algebraic* backbone of quantum processes in ZH. Our first main result is a sound and complete rule set for $\mathbb{L}_{\text{Cosp}}$ with respect to this cospan semantic.

Second, we develop languages $\mathbb{L}_{\text{Span}_k}$ and $\mathbb{L}_{\text{Span}_q}$, which we refer to as Graphical Algebraic Geometry (GAG) over algebraically closed fields and finite fields, respectively. Diagrams in these are built from the same generators as diagrams in $\mathbb{L}_{\text{Cosp}}$, but they are subject to further rewrite rules that express the content of the Nullstellensatz. Denotational semantics are given respectively, as structured spans of affine varieties, and of $\mathbb{F}_q$ -loci of varieties (or, equivalently, of finite sets). We still have the same pseudonormal form (1), but now the vertical wires with polynomials $g_1, \dots, g_n$ denote an affine variety carved out by polynomial constraints, and f_1, f_2 are polynomial maps pointing out of it. This captures the nonlinear *geometric* backbone of quantum processes in ZH. Our second main result is that these languages are sound and complete with respect to their span semantics.

Our languages bear a clear relation to CSP instances with polynomial constraints. As will become clear, a diagram of the form $\text{---} \overline{g} \text{---} \bigcirc$ just is the CSP instance with constraints $g = 0$, while the diagram $\bigcirc \text{---} \overline{g} \text{---} \bigcirc$ is the #CSP problem of counting the number of points satisfying g . Our language, then, gives a compositional and complete rewrite system for networks of CSP instances with polynomial constraints. Through this view of GAG, we show that determining rewriteability of an arbitrary pair of GAG diagrams is #P-hard. In the special case where the field is $\mathbb{F}_2$, this just reduces to a compositional language for SAT instances. This serves as an algebraic elucidation of two ideas already present in the literature: first, that the ZX& calculus completely models “qubit multirelations” [18]; and second, that the ZH calculus can be used to model #SAT instances, and to reason about optimizations of #SAT algorithms [50, 51].

On the other hand, we justify our claim that *GAG is to ZH what GLA is to ZX* by characterizing the Galois-qudit ZH as an extension of GAG over finite fields. Indeed, we show that once we have access to the “classical backbone” carved out by GAG, any process in ZH can be built by consuming just a single basis state in the Fourier basis, up to a finite number of global scalars.

Outline of the paper. We begin in Section 2 by covering the requisite theoretical background on category theory and algebraic geometry. In Section 3, we discuss the Lawvere theory of commutative algebras, which serve as a building block (the “forward fragment”) of our languages. We then construct the (co)span semantic categories of interest, namely, the structured cospan category of commutative algebras, and the structured span category of affine varieties, in Section 4. We prove our first main result in Section 5, where we construct the language $\mathbb{L}_{\text{Cosp}}$ and prove its soundness and completeness for cospans of commutative algebras. The second main result is proven in Section 6, where we construct the languages $\mathbb{L}_{\text{Span}_k}$ and $\mathbb{L}_{\text{Span}_q}$, and prove their soundness and completeness for spans of affine varieties and of rational loci, respectively. In Section 7, we show that closed diagrams in GAG are equivalent to instances of #CSP, and therefore rewriting in GAG is #P-hard. In section 8 we show how the Galois-qudit ZH can be built as an extension of GAG. Finally, in Section 9, we prove the completeness of the qudit ZH calculus by catalysing the completeness of GAG.

2 Background

2.1 Diagrammatic Languages

In this section we present the theory of PROPs as it relates to the construction of our diagrammatic languages. For a more in-depth and theoretical discussion of PROPs, we recommend the excellent note by Lack [52].

Definition 2.1. [55] A Product-and-Permutation-Category (PROP) is a strict symmetric monoidal category C with $Ob(C) \cong \mathbb{N}$, whose monoidal product on objects corresponds to addition of natural numbers.

A PROP morphism from C to $\mathcal{D}$ is strict symmetric monoidal functor such that $1_C \mapsto 1_{\mathcal{D}}$, or in other words, the objects are fixed. A PROP isomorphism is a PROP morphism that is fully faithful.

When we speak of a **presentation** of a PROP, we are speaking about a particular data structure, which we describe here with terminology adopted from the graphical linear algebra literature [12].

Definition 2.2. A **signature** is a set $S = \{f_i : n_i \rightarrow m_i\}_{i \in I}$ where each element has a name, a number of inputs, and a number of outputs, and is pictured as a node in a string diagram:

A **diagrammatic term** over a signature S is an inductive structure constructed as in figure 1.

A **diagram** over S is an equivalence class of diagrammatic terms, where the equivalence relation is the one generated by the coherence axioms of strict symmetric monoidal categories, under the standard interpretation of string diagrams as morphisms in strict symmetric monoidal categories.

Definition 2.3. [12] A symmetric monoidal theory (SMT) is a pair of sets (S, E) , where

- The set S is a signature, whose elements are also referred to as the generators or the spiders;
- The set $E = \{D_j \sim D'_j\}_{j \in \mathcal{J}}$ is a set of pairs of diagrams over S , where each pair relates two diagrams with the same numbers of inputs and outputs. These pairs are called the relations or rewrite rules;

Definition 2.4. For any symmetric monoidal theory (S, E) , there is a corresponding PROP $\langle S \rangle / E$, where:

- Morphisms from n to m are equivalence classes of diagrams over S with n input wires and m output wires, where the equivalence relation is the smallest one containing the axioms E while satisfying the laws of transitivity and substitution;
- Composition is plugging together of wires

$$\begin{array}{c} \vdots \\ \boxed{D_1} \\ \vdots \end{array} \begin{array}{c} \vdots \\ \boxed{D_2} \\ \vdots \end{array} \quad (2)$$

- Monoidal product is side-by-side juxtaposition

$$\begin{array}{c} \vdots \\ \boxed{D_1} \\ \vdots \end{array} \begin{array}{c} \vdots \\ \boxed{D_2} \\ \vdots \end{array} \quad (3)$$

Definition 2.5. An SMT (S, E) presents a PROP C if there is a PROP isomorphism $\langle S \rangle / E \cong C$.

Because a presentation, in this sense, lends itself to diagrammatic representation so naturally, we will use **diagrammatic language** for C as a synonym for a presentation of a C .

Often we have a concrete PROP C in mind (for example, the PROP Mat_R of finite matrices over a ring R), and we want to find a presentation for it. It is useful, then, to think of this as constructing a “syntax category” $\langle S \rangle / E$, and a “semantics functor” $[-] : \langle S \rangle / E \rightarrow C$. If $[-]$ is well-defined as a PROP morphism, we say that E is *sound* for C . If it is full, we say that S is *universal* for C . If it is faithful, we say that E is *complete* for C . If it is all three at the same time, then it is a PROP isomorphism, and so we have a genuine presentation of C .

The simplest useful examples of presentations of PROPs are Lawvere theories of well-behaved algebraic theories, which we now define.

Definition 2.6 (Lawvere Theory). A Lawvere theory is a PROP $\mathbb{L}$ whose monoidal product is also its category-theoretical product, admitting a strictly identity-on-objects and product-preserving functor $\mathbf{N}_0 \rightarrow \mathbb{L}$, where $\mathbf{N}_0$ is a skeleton of the category of finite sets and functions.

Intuitively, a Lawvere theory is a PROP equipped with a cartesian structure (of copying and deleting).

A model of a Lawvere theory $\mathbb{L}$ is a finite product preserving functor $\mathbb{L} \rightarrow \text{Set}$. The models of a fixed Lawvere theory form a category $\text{Mod}(\mathbb{L})$.

Proposition 2.7. (Standard Fact on Lawvere Theories. See for example [13]) Let T be a monad on Set that is finitary (i.e. it preserves filtered colimits). Then there is a Lawvere theory $\mathbb{L}_T$, defined by the equational theory of T , such that

$$\text{Mod}(\mathbb{L}_T) \simeq \text{Alg}(T) \quad (4)$$

where $\text{Alg}(T)$ denotes the Eilenberg-Moore category of T . Moreover, $\mathbb{L}_T$ is equivalent to the opposite of $\text{Kl } T|_{\text{fin}}$, the Kleisli category of T restricted to finite objects.

For instance, suppose we want to find a presentation for the category Mat_R of finite matrices over a ring R . Let T be the monad sending a set X to the free R -module generated by X . Then Mat_R is equivalent to the opposite of $\text{Kl } T|_{\text{fin}}$. The Lawvere theory for finite-dimensional R modules is therefore equivalent to Mat_R . But the Lawvere theory is also, in itself, a neatly presented PROP: the generators are the operations in the Lawvere theory

$$\{ \text{copy}, \text{delete}, \text{add}, \text{zero}, \text{scaling by } r \} \quad \forall r \in R$$

(copy, delete, add, zero, scaling by r) and the rewrite rules are the usual axioms of R -modules. This yields a diagrammatic presentation of the PROP Mat_R , as we wanted.

However, in the GLA literature, the target PROP is usually more complicated than the Kleisli category of an algebraic monad. In particular, it usually has a dagger structure. Building presentations of such PROPs requires us to be able to synthesize larger PROPs out of smaller ones. The simplest way to do this is via PROP sum.

Definition 2.8. [70] Let C and $\mathcal{D}$ be PROPs. Their sum $C + \mathcal{D}$ is their coproduct in the category of PROPs.

Figure 1: Recursive Definition of Diagrammatic Terms

Proposition 2.9. [70] If C has a presentation (S_1, E_1) , and $\mathcal{D}$ has a presentation (S_2, E_2) , then $C + \mathcal{D}$ has presentation $(S_1 \sqcup S_2, E_1 \sqcup E_2)$

In the sum of PROPs, morphisms coming from two different PROPs of course do not interact. To endow interactive behaviour on morphisms of C and $\mathcal{D}$, we need the notion of distributive laws of PROPs.

Definition 2.10. A distributive law is a rewrite rule that distributes morphisms from the two different PROPs past each other:

$$\xrightarrow{f \in C, g \in \mathcal{D}} \sim \xrightarrow{g' \in \mathcal{D}, f' \in C}$$

If E is a collection of such rewrites, then $C +_E \mathcal{D}$ denotes the PROP presented by $(S_1 \sqcup S_2, E_1 \sqcup E_2 \cup E)$.

Note, this is not the traditional way in which distributive laws and their resulting categories are defined, but in the case where C and $\mathcal{D}$ admit presentations (which is the only case we encounter in this paper), this is in fact equivalent to the traditional definition [52].

2.2 Algebraic Geometry

In reviewing the basic algebraic geometry tools required for our purposes, we follow standard texts [20, 23, 37].

We denote by k an arbitrary field, and $\bar{k}$ its algebraic closure. Likewise we denote by $\mathbb{F}_q$ a finite field of size $q = p^n$ for some prime p , and $\bar{\mathbb{F}}_q$ its algebraic closure. The category of finitely generated commutative algebras over k is denoted $\text{CAlg}_k^{\text{f.g.}}$.

2.2.1 Varieties and Polynomial Mappings.

Definition 2.11. Let $I \subset k[x_1, \dots, x_n]$ be an ideal. The **zero-set** of I is:

$$V(I) := \{a \in \bar{k}^n \mid \forall f \in I, f(a) = 0\} \quad (5)$$

An **affine variety** over k is any a zero-set of any ideal of polynomials.

For an intermediate field $k \subset k' \subset \bar{k}$, the k' -**rational locus** of a variety $V \subset \bar{k}^n$ is $V^{(k')} := V \cap (k')^n$; i.e. the set of points in V whose coordinates lie entirely in k' . When we say “a rational locus over k ” without naming an intermediate field, we mean the k -rational locus of a variety over k .

Definition 2.12. Let S be any subset of $\bar{k}^n$. The set of k -polynomials vanishing on S is

$$I_k(S) := \{f \in k[x_1, \dots, x_n] \mid \forall a \in S, f(a) = 0\}$$

It is easy to verify that this set of polynomials forms a radical ideal.

Definition 2.13. Let $V \subset \bar{k}^n$ and $W \subset \bar{k}^m$ be affine varieties over k . A function $\phi : V \rightarrow W$ is a **k -polynomial mapping** if there exists a polynomial tuple $f = (f_1, \dots, f_m) \in (k[x_1, \dots, x_n])^m$ such that

$$\phi(a_1, \dots, a_n) = f(a_1, \dots, a_n)$$

for all $(a_1, \dots, a_n) \in V$. An **isomorphism of varieties** is a polynomial mapping σ which is invertible as a function, such that the inverse function σ^{-1} is itself a polynomial mapping.

The polynomial mappings from V to k forms a commutative algebra over k , called the **coordinate ring** of N , and denoted $k[V]$.

Proposition 2.14. [20] Let V be an affine variety over k . Then

$$k[V] \cong k[x_1, \dots, x_n]/I_k(V).$$

Definition 2.15. (The Categories of Affine Varieties and Rational Loci) [20] For each fixed field k , the polynomial mappings between affine varieties over k forms a category AffVar_k . For each intermediate field $k \subset k' \subset \bar{k}$, there is a full subcategory $\text{AffVar}_k^{(k')} \subset \text{AffVar}_k$ consisting of affine varieties that are entirely k' -rational.

Proposition 2.16. There is a fully faithful contravariant functor $k[-] : \text{AffVar}_k^{\text{op}} \rightarrow \text{CAlg}_k^{\text{f.g.}}$ sending an affine variety V to its coordinate ring $k[V]$.

2.2.2 The Nullstellensatz.

Proposition 2.17 (Hilbert’s Nullstellensatz). [37] Let k be an algebraically closed field, and $J \subset k[x_1, \dots, x_n]$ an ideal. Then

$$I_k(V(J)) = \sqrt{J} \quad (6)$$

Definition 2.18. A commutative algebra A over k is **reduced** if it has no nonzero nilpotents. The full subcategory of $\text{CAlg}_k^{\text{f.g.}}$ consisting of reduced commutative algebras is denoted $\text{CAlg}_k^{\text{f.g., red.}}$.

Proposition 2.19. [23] The functor $(-)_{\text{red}} : \text{CAlg}_k^{\text{f.g.}} \rightarrow \text{CAlg}_k^{\text{f.g., red.}}$ sending $A \mapsto A/\text{nil } A$ is the left-adjoint of the inclusion $\text{CAlg}_k^{\text{f.g., red.}} \hookrightarrow \text{CAlg}_k^{\text{f.g.}}$.

Proposition 2.20. [23] If k is an algebraically closed field, then the coordinate ring functor $k[-]$ gives an anti-equivalence of categories

$$k[-] : \text{AffVar}_k^{\text{op}} \simeq \text{CAlg}_k^{\text{f.g., red.}}. \quad (7)$$

Denote its inverse functor (up to isomorphism) as

$$\text{Spec} : \text{CAlg}_k^{\text{f.g., red.}} \rightarrow \text{AffVar}_k^{\text{op}} \quad (8)$$

We now turn our attention to the case of finite fields. Note: while affine varieties over algebraically closed fields are “rare” among the subsets of k^n , any subset of $\mathbb{F}_q^n$ is an affine variety over $\mathbb{F}_q$.

Proposition 2.21. The category $\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)}$ of rational loci over $\mathbb{F}_q$ is equivalent to the category FinSet of finite sets and relations.

PROOF. It is well known [31, 54] that any subset of $\mathbb{F}_q^n$ is an affine variety, and any function between them is polynomial. $\square$

However our results are most easily read if we think in terms of polynomial constraints and morphisms, rather than subsets and functions. We retain the notation $\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)}$ as a reminder of this “attitude”.

Proposition 2.22 (Finite Field Nullstellensatz). *Let $J \subset \mathbb{F}_q[x_1, \dots, x_n]$ be any ideal of polynomials over a finite field. Then*

$$I_{\mathbb{F}_q}(V^{(\mathbb{F}_q)}(J)) = J + \Gamma_q^n \quad (9)$$

where $\Gamma_q^n := (x_1^q - x_1, \dots, x_n^q - x_n)$. [30]

Definition 2.23. For a finite field $\mathbb{F}_q$, a commutative algebra A over $\mathbb{F}_q$ is called q -**reduced**¹ if for every $f \in A$, $f^q = f$. The q -reduced algebras form a full subcategory $\text{CAlg}_{\mathbb{F}_q}^{\text{f.g.}, \text{qred.}} \subset \text{CAlg}_{\mathbb{F}_q}^{\text{f.g.}}$.

Definition 2.24. For a finite field $\mathbb{F}_q$ and a finitely generated commutative algebra A over it, define its q -radical as the ideal generated as follows:

$$\Gamma_q(A) := (f^q - f : f \in A) \quad (10)$$

Remark 2.25. If $\{x_1, \dots, x_n\}$ generate A over $\mathbb{F}_q$ then

$$\Gamma_q(A) = \Gamma_q^n = (x_1^q - x_1, \dots, x_n^q - x_n). \quad (11)$$

Proposition 2.26. The functor $(-)^{\text{qred.}} : \text{CAlg}_{\mathbb{F}_q}^{\text{f.g.}} \rightarrow \text{CAlg}_{\mathbb{F}_q}^{\text{f.g.}, \text{qred.}}$ mapping $A \mapsto A/\Gamma_q(A)$ is left-adjoint to the inclusion.

Proposition 2.27. For a finite field $\mathbb{F}_q$, the coordinate ring functor $\mathbb{F}_q[-]$ restricted to the $\mathbb{F}_q$ -rational loci defines an equivalence of categories

$$\mathbb{F}_q[-] : \text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q) \text{op}} \simeq \text{CAlg}_{\mathbb{F}_q}^{\text{f.g.}, \text{qred.}} \quad (12)$$

Denote its inverse functor as Spec .

PROOF. Because $\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)} \simeq \text{FinSet}$, so this is really just a non-binary version of the well known Stone duality between finite boolean algebras and finite sets [44]. The q -reduced commutative algebras over $\mathbb{F}_q$ correspond one-to-one with $\mathbb{F}_q$ -valued functions out of finite sets, and $\mathbb{F}_q[-]$ sends a set to its algebra of $\mathbb{F}_q$ -valued functions [54]. For a more algebraic perspective see also [34]. $\square$

Notation. Denote the q -reduced free commutative algebras

$$\mathcal{R}_q^n := S_{\mathbb{F}_q}(n)/\Gamma_q^n, \quad (13)$$

and denote the full subcategory of $\text{CAlg}_{\mathbb{F}_q}^{\text{f.g.}}$ consisting of such algebras as $\text{Poly}_{\mathbb{F}_q}^{\text{qred.}}$, and F_q its inclusion functor.

3 The Polynomial Fragment

Consider the free-forgetful adjunction

$$\begin{array}{ccc} \text{Set} & \xrightarrow{S_k} & \text{CAlg}_k \\ & \lrcorner & \uparrow U \\ & & \end{array}$$

On finite sets n , $S_k(n)$ is just the polynomial algebra $k[x_1, \dots, x_n]$. Then let $T_k = U \circ S_k$ be the associated monad.

¹This is our terminology. In finite field error correction literature this is just called “reduced” [30], but we need to avoid confusion with the aforementioned more standard notion of reduction from algebra.

Definition 3.1. Let Poly_k be the full subcategory of $\text{CAlg}_k^{\text{f.g.}}$ given by the image of S_k restricted to finite sets. In other words, let Poly_k be the Kleisli category of T_k restricted to finite sets, corresponding to the polynomial algebras $k[x_1, \dots, x_n]$.

Notation (Sharps and Flats). It is worth being careful about the equivalence between Poly_k and $\text{Kl } T_k|_{\text{fin}}$, the Kleisli category of T_k restricted to finite objects. If $f \in (k[x_1, \dots, x_n])^m$ is a tuple of polynomials, denote by $f^\#$ its unique extension to an algebra morphism $S_k(m) \rightarrow S_k(n)$. This acts on a polynomial $g(y_1, \dots, y_m)$ by substituting y_j with $f_j(x_1, \dots, x_n)$. Notice the contravariance implicit in this: algebra morphisms point and compose in the opposite direction than polynomials. Conversely, if $\varphi : S_k(m) \rightarrow S_k(n)$ is an algebra morphism, denote by $\varphi^b : m \rightarrow S_k(n)$ the corresponding tuple of polynomials defined by $\varphi_j^b = \varphi(x_j)$.

Recall from section 2.1 that for any finitary monad T , there is an equivalence $\text{Kl } T|_{\text{fin}} \simeq \mathbb{L}_T^{\text{op}}$, where $\mathbb{L}_T$ denotes the Lawvere theory corresponding to T . In our case, the Lawvere theory is that of commutative algebras over k , which we denote $\mathbb{L}_{\text{CAlg}_k}$. Then:

Proposition 3.2. The generators and rewrite rules depicted in figure 2 form a presentation of the PROP $\mathbb{L}_{\text{CAlg}_k} \simeq \text{Poly}_k^{\text{op}}$.

PROOF. This is the standard presentation of the Lawvere theory of commutative algebras over k , with the following interpretation for the diagrams: the white dots $\text{---}\bigcirc\text{---}$ and $\text{---}\bigcirc$ are read as copying and its counit deleting, the grey dots $\text{---}\bigcirc\text{---}$ and $\bigcirc\text{---}$ are read as adding and its unit zero, the yellow half-moons $\text{---}\bigcup\text{---}$ and $\bigcup\text{---}$ are read as multiplication and its unit one, and the “squeeze” gadgets $\text{---}\kappa\text{---}$ labelled by elements of k are read as the scaling operation by the field k on a k -commutative algebra. The rewrite rules of the Lawvere theory guarantee that each (finite variable) polynomial with coefficients in k can be expressed as a diagram in this language uniquely up to rewrites. $\square$

Notation (Scalable Notation). We can now unambiguously introduce scalable notation for diagrams in $\mathbb{L}_{\text{CAlg}_k}$. For $n \in \mathbb{N}$ we define n -labelled wire and gates, as depicted in figure 3.

For every polynomial tuple $f \in (k[x_1, \dots, x_n])^m$, we abbreviate the diagram (unique up to rewrites) that corresponds to $f^\#$ in $\mathbb{L}_{\text{CAlg}_k}$ as $n \text{---}\overline{f}\text{---} m$.

For example, for the polynomial tuple $f = (x_1 + x_2, x_1x_3 + x_1^2) \in (k[x_1, x_2, x_3])^2$, we have

$$3 \text{---}\overline{f}\text{---} 2 = \begin{array}{c} x_1 \text{---}\bigcirc\text{---} x_1 + x_2 \\ x_2 \text{---}\bigcirc\text{---} \\ x_3 \text{---}\bigcirc\text{---} x_1x_3 + x_1^2 \end{array} \quad (14)$$

Notice that the contravariance between morphism composition and polynomial composition has been inherited by our diagrammatic language. Diagrammatically, everything is drawn in the direction of the Lawvere theory $\mathbb{L}_{\text{CAlg}_k}$. So $n \text{---}\overline{f}\text{---} m$ corresponds to a tuple of polynomials $(k[x_1, \dots, x_n])^m$, which corresponds to a morphism $f^\# \in \text{Poly}_k(m, n)$. The necessity for this will become clear in section 6 when we construct the language for spans of affine varieties.

Figure 2: The Theory $\mathbb{L}_{\text{CALg}_K}$ of Commutative Algebras over k **Figure 3: Scalable Notation for $\mathbb{L}_{\text{CALg}_K}$** 

Proposition 3.3. *From the rewrite rules of $\mathbb{L}_{\text{CALg}_k}$ it is possible to derive the rewrite rules about polynomials in the scalable notation, as depicted in figure 4.*

PROOF. See appendix A. $\square$

4 (Co)span Semantics

In this section we describe the target semantic categories of graphical commutative algebra and graphical algebraic geometry. We begin by recalling the definition of structured (co)spans, which is of particular importance here:

Definition 4.1. [5] Let $F : \mathcal{A} \rightarrow \mathcal{X}$ be a functor where $\mathcal{X}$ is a category with pullbacks. Define the bicategory of **structured spans** ${}_F\text{Sp}(\mathcal{X})$: its objects are those of $\mathcal{A}$; its 1-cells are pairs of $\mathcal{X}$ morphisms of the form $FA \leftarrow S \rightarrow FB$ with $A, B \in \mathcal{A}$, which compose via pullback

and its 2-cells are commuting diagrams of the form

Quotienting the categories of 1-cells of ${}_F\text{Sp}(\mathcal{X})$ by the 2-isomorphisms, we obtain a 1-category ${}_F\text{Span}(\mathcal{X})$, whose objects are those of $\mathcal{A}$, and morphisms are isomorphism classes of spans $FA \leftarrow S \rightarrow FB$.

For a functor $F : \mathcal{A} \rightarrow \mathcal{X}$ where $\mathcal{X}$ has pushouts, the bicategory of **structured cospans** ${}_F\text{Csp}(\mathcal{X})$ and the 1-category ${}_F\text{Cosp}(\mathcal{X})$ are defined dually to the above, with 1-cells of the form $FA \rightarrow S \leftarrow FB$ and composition given by pushout instead of pullback.

The following is an immediate well-known consequence of the dual nature of the definitions of structures cospans and spans:

Proposition 4.2. *If $F : \mathcal{A} \rightarrow \mathcal{X}$ is a functor and $\mathcal{X}$ has pullbacks, then $\mathcal{X}^{op}$ has pushouts, and there is an equivalence*

$${}_F\text{Span}(\mathcal{X}) \simeq {}_{F^{op}}\text{Cosp}(\mathcal{X}^{op}) \quad (15)$$

where $F^{op} : \mathcal{A}^{op} \rightarrow \mathcal{X}^{op}$ is the dual functor of F .

Definition 4.3. In the structured span construct, the category $\mathcal{A}$ embeds into ${}_F\text{Span}(\mathcal{X})$ both covariantly by the graph embedding:

$$G_{\text{Span}} : \left(A \xrightarrow{f} B \right) \mapsto \left(FA = FA \xrightarrow{Ff} FB \right)$$

and contravariantly by the cograph embedding:

$$G_{\text{Span}}^{op} : \left(A \xrightarrow{f} B \right) \mapsto \left(FB \xleftarrow{Ff} FA = FA \right)$$

Similarly in the structured cospan construct, the category $\mathcal{A}$ embeds into ${}_F\text{Cosp}(\mathcal{X})$ covariantly by the graph embedding:

$$G_{\text{Cosp}} : \left(A \xrightarrow{f} B \right) \mapsto \left(FA \xrightarrow{Ff} FB = FB \right)$$

and contravariantly by the cograph embedding:

$$G_{\text{Cosp}}^{op} : \left(A \xrightarrow{f} B \right) \mapsto \left(FB = FB \xleftarrow{Ff} FA \right)$$

The following are not new results, but are recalled here as we shall need it immediately.

Proposition 4.4. *For any field k , the category $\text{CALg}_k^{f.g.}$ of finitely-generated commutative algebras over k has pushouts.*

PROOF. To construct the pushout: suppose $A = k[x_1, \dots, x_n]/I_A$, $B = k[y_1, \dots, y_m]/I_B$, $C = k[z_1, \dots, z_r]/I_C$ with maps $A \xleftarrow{\phi} C \xrightarrow{\psi} B$. Then

$$A \otimes_C B = \frac{k[x_1, \dots, x_n, y_1, \dots, y_m]}{I_A + I_B + \sum_{i=1}^r (\phi(z_i) - \psi(z_i))} \quad (16)$$

Where, by a slight abuse of notation, I_A, I_B denote the images of I_A, I_B via the embeddings

$$k[x_1, \dots, x_n] \hookrightarrow k[x_1, \dots, x_n, y_1, \dots, y_m] \hookleftarrow k[y_1, \dots, y_m]$$

$\square$

Corollary 4.5. *If k is either algebraically closed or finite, the category $\text{AffVar}_k^{(k)}$ has pullbacks.*

Definition 4.6 (Semantic Category of Graphical Commutative Algebra). Let $F : \text{Poly}_k \hookrightarrow \text{CALg}_k^{f.g.}$ be the inclusion of the polynomial algebras into the finitely generated algebras. Then apply the structured cospans construction to obtain a category ${}_F\text{Cosp}(\text{CALg}_k^{f.g.})$. The objects of this category are polynomial algebras, and the morphisms are structured cospans of the form

$$S_k(n) \xrightarrow{f} A \xleftarrow{g} S_k(m) \quad (17)$$

where A is some finitely generated commutative algebra over k . Such a cospan is, in other words, a choice of n elements of A (corresponding to the left leg), and a choice of m elements of A (corresponding to the right leg). These cospans compose as usual by pushout.

Definition 4.7 (Semantic Category of Graphical Algebraic Geometry). Let k be an algebraically closed field and $\mathbb{F}_q$ a finite field. Apply the structured span construction with respect to the inclusions of free spaces $k^n, \mathbb{F}_q^n$ into the respective categories of affine varieties to obtain categories ${}_G\text{Span}(\text{AffVar}_k)$ and ${}_{G_q}\text{Span}(\text{AffVar}_{\mathbb{F}_q})$. Morphisms in ${}_G\text{Span}(\text{AffVar}_k)$ are spans of polynomial maps $k^n \leftarrow V \rightarrow k^m$ where V is an affine variety.

Proposition 4.8. *The three semantic categories are PROPs.*

PROOF. The objects of ${}_F\text{Cosp}(\text{CALg}_k^{f.g.})$ are the polynomial algebras $k[x_1, \dots, x_n]$, the monoidal product on objects is $k[x_1, \dots, x_n] \otimes k[y_1, \dots, y_m] = k[x_1, \dots, x_n, y_1, \dots, y_m]$; and on morphisms by the tensor-product of algebra morphisms on both legs of the cospans.

The braidings are given by the graphs of

$$\sigma : k[x_1, \dots, x_n, y_1, \dots, y_m] \rightarrow k[y_1, \dots, y_m, x_1, \dots, x_n] \quad (18)$$

The proofs for the other two categories are similar. $\square$

The semantic categories for GCA and GAG are related, and we now explain this relation. The structured (co)span construction is “functorial”:

Figure 4: Rules for Scalable Notation

Proposition 4.9. [5] Given $F : \mathcal{A} \rightarrow \mathcal{X}$ and $F' : \mathcal{B} \rightarrow \mathcal{Y}$, with $\mathcal{X}, \mathcal{Y}$ both having pullbacks, if there is a commutative square of functors

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{F} & \mathcal{X} \\ \Phi \downarrow & & \downarrow \Psi \\ \mathcal{B} & \xrightarrow{F'} & \mathcal{Y} \end{array}$$

and Ψ preserves pullbacks, then there is a functor

$$\text{Span}(\Psi, \Phi) : {}_F \text{Span}(\mathcal{X}) \rightarrow {}_{F'} \text{Span}(\mathcal{Y}) \quad (19)$$

which sends the structured span $(FA_1 \xleftarrow{f} X \xrightarrow{g} FA_2)$ to a structured span in ${}_F \text{Span}(\mathcal{Y})$ by hitting everything with Ψ . The dual statement is true for structured cospans.

Corollary 4.10. In particular, in the situation of proposition 4.9, if Φ, Ψ are both equivalences of categories, then the induced functor ${}_F \text{Span}(\mathcal{X}) \rightarrow {}_{F'} \text{Span}(\mathcal{Y})$ is also an equivalence of categories.

In particular, recall from proposition 2.26 that there are functors

$$\begin{aligned} (-)_{\text{red}} : \text{CAlg}_k^{f.g.} &\rightarrow \text{CAlg}_k^{f.g., \text{red.}} \\ (-)_{q\text{red}} : \text{CAlg}_{\mathbb{F}_q}^{f.g.} &\rightarrow \text{CAlg}_{\mathbb{F}_q}^{f.g., q\text{red.}} \end{aligned} \quad (20)$$

each of which are left-adjoint to the inclusion in the opposite direction, and therefore they preserve pushouts. Moreover, they commute with the inclusions of the “free” algebras $F : \text{Poly}_k \hookrightarrow \text{CAlg}_k^{f.g.}$ and $F_q : \text{Poly}_{\mathbb{F}_q}^{q\text{red.}} \hookrightarrow \text{CAlg}_{\mathbb{F}_q}^{f.g.}$. The functoriality of the structured cospan construction (proposition 4.9) implies there are functors

$$\begin{aligned} {}_F \text{Cosp}(\text{CAlg}_k^{f.g.}) &\xrightarrow{(-)_{\text{red}}} {}_F \text{Cosp}(\text{CAlg}_k^{f.g., \text{red.}}) \\ {}_F \text{Cosp}(\text{CAlg}_{\mathbb{F}_q}^{f.g.}) &\xrightarrow{(-)_{q\text{red}}} {}_{F_q} \text{Cosp}(\text{CAlg}_{\mathbb{F}_q}^{f.g., q\text{red.}}) \end{aligned} \quad (21)$$

Now recall that if k is algebraically closed, then there is an anti-equivalence (2.20)

$$\text{Spec} : \text{CAlg}_k^{f.g., \text{red.}} \simeq \text{AffVar}_k^{\text{op}} \quad (22)$$

and if $\mathbb{F}_q$ is finite of size q , then there is an anti-equivalence (2.27)

$$\text{Spec} : \text{CAlg}_{\mathbb{F}_q}^{f.g., q\text{red.}} \simeq \text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)^{\text{op}}} \quad (23)$$

Moreover, it is easy to check that these commute with the inclusions F, F_q, G, G_q in the obvious way. So using the duality between span

and cospan (4.2) we obtain maps

$$\begin{aligned} {}_F \text{Cosp}(\text{CAlg}_k^{f.g.}) &\xrightarrow{(-)_{\text{red}}} {}_F \text{Cosp}(\text{CAlg}_k^{f.g., \text{red.}}) \simeq {}_G \text{Span}(\text{AffVar}_k) \\ {}_{F_q} \text{Cosp}(\text{CAlg}_{\mathbb{F}_q}^{f.g.}) &\xrightarrow{(-)_{q\text{red}}} {}_{F_q} \text{Cosp}(\text{CAlg}_{\mathbb{F}_q}^{f.g., q\text{red.}}) \simeq {}_{G_q} \text{Span}(\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)}) \end{aligned} \quad (24)$$

5 Graphical Commutative Algebra

We now work towards a diagrammatic presentation of the structured cospan category ${}_F \text{Cosp}(\text{CAlg}_k^{f.g.})$. All lemmas, propositions, and theorems in this section are proven in appendix B, unless otherwise specified.

5.1 Defining the Calculus $\mathbb{L}_{\text{Cosp}}$

Definition 5.1. Construct the PROP $\mathbb{L}_{\text{Cosp}} = \mathbb{L}_{\text{CAlg}_k} +_E \mathbb{L}_{\text{CAlg}_k}^{\text{op}}$ where E is the set of rewrite rules displayed in figure 5. We supply this PROP with an intended semantic functor

$$[-] : \mathbb{L}_{\text{Cosp}} \rightarrow {}_F \text{Cosp}(\text{CAlg}_k^{f.g.}) \quad (25)$$

by mapping each generator in $\mathbb{L}_{\text{CAlg}_k}$ via the cograph embedding, and each generator in $\mathbb{L}_{\text{CAlg}_k}^{\text{op}}$ via the graph embedding.

$$\begin{array}{ccc} \mathbb{L}_{\text{CAlg}_k} & \xrightarrow{\quad} & \text{Poly}_k^{\text{op}} \\ \downarrow & & \searrow G_{\text{Csp}} \\ \mathbb{L}_{\text{CAlg}_k} + \mathbb{L}_{\text{CAlg}_k}^{\text{op}} & \xrightarrow{\quad} & \mathbb{L}_{\text{CAlg}_k} +_E \mathbb{L}_{\text{CAlg}_k}^{\text{op}} \xrightarrow{[-]} {}_F \text{Cosp}(\text{CAlg}_k^{f.g.}) \\ \uparrow & & \nearrow G_{\text{Csp}}^{\text{op}} \\ \mathbb{L}_{\text{CAlg}_k}^{\text{op}} & \xrightarrow{\quad} & \text{Poly}_k \end{array}$$

We must first prove that the functor $[-]$ is well-defined, which is equivalent to the following statement:

Proposition 5.2 (Cospan Soundness). *Every rewrite rule in E is sound with respect to the intended semantic $[-]$.*

Once well-definedness has been established, we can now derive the following useful rewrite rules from the given rules:

Lemma 5.3. *The following are some useful derived rules of $\mathbb{L}_{\text{Cosp}}$:*

$$\begin{aligned} \text{Special} &: \text{Diagram} = \text{Diagram} \quad (\text{special}) \\ \text{Poly-trp} &: \text{Diagram} = \text{Diagram} \quad \forall f \in (k[x_1, \dots, x_n])^m \quad (\text{poly-trp}) \end{aligned}$$

Figure 5: Additional Rewrite Rules for $\mathbb{L}_{\text{Cosp}}$ 

5.2 Universality and Completeness

To consider the nature of the (essential) image of $[-]$ in $F \text{Cosp}(\text{CAlg}_k^{f.g.})$, we first prove the following sequence of lemmas in the language $\mathbb{L}_{\text{Cosp}}$, which will allow us to introduce an essential piece of syntactic sugar for summarizing a diagram.

Lemma 5.4. *For any $f \in k[x_1, \dots, x_n]$, the following is derivable from the rewrite rules of $\mathbb{L}_{\text{Cosp}}$:*

So we just speak of gadgets of the form

Lemma 5.5. *For any $f, g \in k[x_1, \dots, x_n]$, the following is derivable from the rewrite rules of $\mathbb{L}_{\text{Cosp}}$:*

Lemma 5.6. *Let $f_1, \dots, f_m \in k[x_1, \dots, x_n]$, and pick some f inside the ideal $(f_1, \dots, f_m)$. Then the following is derivable from the rewrite rules of $\mathbb{L}_{\text{Cosp}}$:*

Lemmas 5.5 and 5.6 mean that we can coherently define the following gadget:

Definition 5.7. Let $I \subset k[x_1, \dots, x_n]$ be an ideal. Since $k[x_1, \dots, x_n]$ is Noetherian [23], there exists a finite set of polynomials $f_1, \dots, f_m \in k[x_1, \dots, x_n]$ such that $I = (f_1, \dots, f_m)$. Then define

Note that neither the choice of the basis $f_1, \dots, f_m$, nor the ordering of them, matters in the definition, since any two such choices give diagrams which are rewriteable to each other per lemmas 5.5 and 5.6. For concreteness, we may always choose the reduced Grobner basis with respect to some chosen monomial ordering.

Corollary 5.8. *Idempotence $\begin{array}{c} \triangle \\ I \\ \circ \end{array} \begin{array}{c} \triangle \\ I \\ \circ \end{array} = \begin{array}{c} \triangle \\ I \\ \circ \end{array}$ is provable in $\mathbb{L}_{\text{Cosp}}$.*

We now explain the semantics of these gadgets.

Proposition 5.9 (Quotient Gadgets). *The semantic of the gadget*

is (any finite presentation of) the finitely generated commutative algebra defined by I . More precisely, if $I \subset k[x_1, \dots, x_n]$ is any ideal, then

$$\left[\begin{array}{c} \triangle \\ I \\ \circ \end{array} \right] = (S_k(n) \twoheadrightarrow S_k(n)/I \leftarrow S_k(n))$$

where both legs are the canonical projections π_I against I .

This is essentially what brings us from a language for Poly_k to a language that has full information about $\text{CAlg}_k^{f.g.}$, which forces us to introduce the following notation:

Notation. If $A = S_k(n)/I$, and $f \in (k[x_1, \dots, x_n])^m$, denote by $f_I^\# : S_k(m) \rightarrow A$ the algebra morphism one gets by passing to the quotient:

$$S_k(m) \xrightarrow{f^\#} S_k(n) \twoheadrightarrow S_k(n)/I = A \quad (28)$$

Or equivalently, the algebra morphism one gets by reducing f against I component-wise to obtain $\bar{f}_I \in A^m$, and then taking its extension to an algebra morphism $f_I^\# : S_k(m) \rightarrow A$.

Proposition 5.10 (Cospan Universality). *For any ideal $I \subset k[x_1, \dots, x_n]$ and tuples of polynomials $f \in (k[x_1, \dots, x_n])^m$ and $g \in (k[x_1, \dots, x_n])^{m'}$,*

$$\left[\begin{array}{c} \triangle \\ I \\ \circ \end{array} \right] = \left(S_k(m) \xrightarrow{f_I^\#} A \xleftarrow{g_I^\#} S_k(m') \right) \quad (29)$$

where $A = S_k(n)/I$. Since every algebra morphism $S_k(m) \rightarrow A$ is equal to $f_I^\#$ for some f , so $[-] : \mathbb{L}_{\text{Cosp}} \rightarrow F \text{Cosp}(\text{CAlg}_k^{f.g.})$ is full.

It remains now to prove the completeness of the language $\mathbb{L}_{\text{Cosp}}$. We do this by reducing diagrams to a pseudo-normal form as follows:

Definition 5.11. A diagram D in $\mathbb{L}_{\text{Cosp}}$ is said to be in **cospan form** if it is draw as

for some ideal I and some polynomial tuples f, g .

Proposition 5.12 (Cospan Normal Form). *Every diagram in $\mathbb{L}_{\text{Cosp}}$ can be rewritten into cospan form.*

Thus, to show completeness of $\mathbb{L}_{\text{Cosp}}$, it suffices to show that, for any two diagrams in cospan form, if they have the same semantic in ${}_F \text{Cosp}(\text{Alg}_g^{\text{f.g.}})$, then they can be rewritten into each other. We do this via the following lemmas:

Lemma 5.13. *Let $I \subset k[x_1, \dots, x_n]$ be an ideal, and let $f, g \in (k[x_1, \dots, x_n])^m$ be any two polynomial tuples such that $f - g \in I^m$. That is, let f, g be such that $f_I^\# = g_I^\#$. Then the following diagram rewrite is derivable in $\mathbb{L}_{\text{Cosp}}$:*

$$\begin{array}{c} \triangle I \\ | \\ \bigcirc \\ | \\ \rightarrow f \rightarrow \end{array} = \begin{array}{c} \triangle I \\ | \\ \bigcirc \\ | \\ \rightarrow g \rightarrow \end{array} \quad (31)$$

Lemma 5.14. *Suppose $I \subset S_k(n)$ and $J \subset S_k(m)$ are ideals of polynomials and $f \in (S_k(n))^m$. Suppose $f_I^\# : S_k(m) \rightarrow S_k(n)/I$ satisfies $J \subset \ker f_I^\#$. Then the following rewrite holds:*

$$\text{---} \circlearrowleft \triangle I \text{---} \Rightarrow f \text{---} \circlearrowleft \triangle J \text{---} = \text{---} \circlearrowleft \triangle I \text{---} \Rightarrow f \text{---}$$

Lemma 5.15. *Suppose $I \subset S_k(n)$ and $J \subset S_k(m)$ are ideals, $\alpha : S_k(m)/J \rightarrow S_k(n)/I$ is an isomorphism of algebras, and $\sigma \in (k[x_1, \dots, x_n])^{\text{st}}$, $\tau \in (k[y_1, \dots, y_m])^n$ are a pair of polynomial tuples such that they represent α, α^{-1} respectively, i.e. such that the following commutes:*

$$\begin{array}{ccccc} S_k(m) & \xrightarrow{\pi_J} S_k(m)/J & \xleftarrow{\pi_J} & S_k(m) \\ \sigma^\# \downarrow & \alpha^{-1} \uparrow \downarrow \alpha & & \uparrow \tau^\# \\ S_k(n) & \xrightarrow{\pi_I} S_k(n)/I & \xleftarrow{\pi_I} & S_k(n) \end{array}$$

Then the following rewrite holds:

$$\begin{array}{c} \triangle J \\ | \\ \text{---} \bigcirc \text{---} \rightleftarrows \end{array} = \begin{array}{c} \triangle I \\ | \\ \text{---} \leftleftarrows \bigcirc \text{---} \end{array} \quad (32)$$

By composing $\text{---}\overrightarrow{\sigma}\text{---}$ on the right to both sides of the equation in 5.15, we obtain:

Corollary 5.16. *If $\alpha : S_k(m)/J \rightarrow S_k(n)/I$ is an isomorphism of algebras, and $\sigma \in (k[x_1, \dots, x_n])^m$ represents α as in lemma 5.15, then*

The diagram shows an equality between two expressions. On the left, a triangle labeled J is connected to a circle, which is then connected to a horizontal line. On the right, a triangle labeled I is connected to a circle, which is then connected to two horizontal lines, each passing through a hexagon labeled σ .

Lemmas 5.13, 5.14, and 5.15 suffice to show that any two diagrams in cospan normal form which have the same semantic in ${}_F\text{Cosp}(\text{CAlg}_{\mathbf{g}}^{\text{f.g.}})$ can be rewritten into each other. And therefore:

Proposition 5.17. *The functor $[-]$ is faithful. That is, $\mathbb{L}_{\text{Cosp}}$ is complete as a language for ${}_F\text{Cosp}(\text{CAlg}_k^{\text{f.g.}})$.*

We have now completed the demonstration of our first main theorem:

Theorem 5.18. *The functor $[-] : \mathbb{L}_{\text{Cosp}} \rightarrow {}_F \text{Cosp}(\text{CAlg}_k^{\text{f.g.}})$ is an isomorphism of PROPs. Thus $\mathbb{L}_{\text{Cosp}}$ is a sound, universal and complete language for ${}_F \text{Cosp}(\text{CAlg}_k^{\text{f.g.}})$.*

PROOF. Propositions 5.2, 5.10, and 5.17 together imply theorem 5.18. $\square$

6 Graphical Algebraic Geometry

Our focus now turns from algebra to geometry. In this section k will always denote an algebraically closed field, and $\mathbb{F}_q$ will always denote a finite field of size q . All proofs are contained in appendix C unless otherwise specified.

Recall from equation 24 that there are two functors

$$\begin{aligned} {}_F \text{Cosp}(\text{CAlg}_k^{\text{f.g.}}) &\xrightarrow{\text{Spec}(-)_{\text{red}}} {}_G \text{Span}(\text{AffVar}_k) \\ {}_F \text{Cosp}(\text{CAlg}_{\mathbb{F}_q}^{\text{f.g.}}) &\xrightarrow{\text{Spec}(-)_{q\text{red}}} {}_{G_q} \text{Span}(\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)}) \end{aligned} \quad (33)$$

We now seek diagrammatic presentations for ${}_G \text{Span}(\text{AffVar}_k)$ and ${}_{G_q} \text{Span}(\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)})$. Since we already have a presentation $\mathbb{L}_{\text{Cosp}} \cong \mathbb{F} \text{Cosp}(\text{CAlg}_k^{\text{f.g.}})$, so we seek to find $\mathbb{L}_{\text{Span}_k}$ and $\mathbb{L}_{\text{Span}_q}$ that fit into the following commutative diagrams:

$$\begin{array}{ccc}
\mathbb{L}\mathbf{Cosp} & \xrightarrow{[-]}_F \mathbf{Cosp}(\mathbf{CAlg}_k^{\mathbf{f.g.}}) & \mathbb{L}\mathbf{Cosp} & \xrightarrow{[-]}_F \mathbf{Cosp}(\mathbf{CAlg}_k^{\mathbf{f.g.}}) \\
\Downarrow & & \Downarrow & \\
\mathbb{L}\mathbf{Span}_k & \xrightarrow{[-]}_G \mathbf{Span}(\mathbf{AffVar}_k) & \mathbb{L}\mathbf{Span}_q & \xrightarrow{[-]}_{G_q} \mathbf{Span}(\mathbf{AffVar}_{\mathbb{F}_q}) \\
& & & \text{Spec}(-)_{red} \quad \text{Spec}(-)_{qred}
\end{array}$$

such that $[-]_k$ and $[-]_q$ are both isomorphisms of PROPs.

6.1 GAG over Algebraically Closed Fields

Definition 6.1. Let $\mathbb{L}_{\text{Span}_k}$ be the quotient of $\mathbb{L}_{\text{Cosp}}$ defined by the following additional rewrite rule:

 (red)

Proposition 6.2. *The PROP morphism*

$$\mathbb{L}_{\text{Cosp}} \xrightarrow{\text{Spec}[-]_{\text{red}}} {}_G\text{Span}(\text{AffVar}_k) \quad (34)$$

factors through $\mathbb{L}_{\text{Span}_k}$. In other words, rule (red) is sound for affine varieties over an algebraically closed field.

Thus we obtain a PROP morphism

$$\mathbb{L}_{\text{Span}_k} \xrightarrow{[-]_k} \text{Span}(\text{AffVar}_k) \quad (35)$$

It remains to show that this morphism is faithful: in other words, that our rewrite rules are complete.

Lemma 6.3. *Let $I \subset k[x_1, \dots, x_n]$ be an ideal. The following is deriveable from the rewrite rules of $\mathbb{L}_{\text{Span}_k}$:*

$$\begin{array}{c} \triangle \\ | \\ \text{---} \end{array} I = \begin{array}{c} \triangle \\ | \\ \text{---} \end{array} \sqrt{I} \quad (36)$$

Proposition 6.4. *The semantic map $\mathbb{L}_{\text{Span}_k} \xrightarrow{[-]_k} {}_G\text{Span}(\text{AffVar}_k)$ is faithful. In other words, $\mathbb{L}_{\text{Span}_k}$ is complete for ${}_G\text{Span}(\text{AffVar}_k)$.*

Since $[-]_k$ also inherits the fullness of $[-]$:

Theorem 6.5. *The semantic map $\mathbb{L}_{\text{Span}_k} \xrightarrow{[-]_k}_G \text{Span}(\text{AffVar}_k)$ is an isomorphism of PROPs; $\mathbb{L}_{\text{Span}_k}$ is a universal, sound, and complete language for $_G \text{Span}(\text{AffVar}_k)$.*

6.2 GAG over Finite Fields

The recipe for obtaining a language for spans of rational loci of affine varieties over finite fields is almost identical to the one used for spans of affine varieties over closed fields.

Definition 6.6. Let $\mathbb{L}_{\text{Span}_q}$ be the quotient of $\mathbb{L}_{\text{Cosp}}$ by the following additional rewrite rule:

$$\text{---} \circ \text{---} \begin{array}{c} \vdots \\ q \end{array} \text{---} = \text{---} \quad (\text{qred})$$

Proposition 6.7. *The PROP morphism*

$$\mathbb{L}_{\text{Cosp}} \xrightarrow{\text{Spec}[-]_{\text{qred}}} {}_{G_q} \text{Span}(\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)}) \quad (37)$$

factors through $\mathbb{L}_{\text{Span}_q}$. In other words, the rule *qred* is sound with respect to $\mathbb{F}_q$ -rational loci.

Thus we obtain a PROP morphism

$$\mathbb{L}_{\text{Span}_q} \xrightarrow{[-]_q} {}_{G_q} \text{Span}(\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)}) \quad (38)$$

Now to show that this morphism is faithful:

Lemma 6.8. *For $\Gamma_q^n = \{x_1^q, \dots, x_n^q\}$, the following is derivable from*

the rewrite rules of $\mathbb{L}_{\text{Span}_q}$: $\text{---} \circ \text{---} \begin{array}{c} \triangle \\ \Gamma_q^n \end{array} \text{---} = \text{---}$

Proposition 6.9. *The semantic map $[-]_q$ is faithful. In other words, the rules of $\mathbb{L}_{\text{Span}_q}$ are complete.*

Theorem 6.10. *The semantic map $[-]_q$ is an isomorphism of PROPs.*

6.3 Matrix Semantics for GAG

Given a structured span of affine varieties over a field k (not necessarily algebraically closed) of the form $k^n \xleftarrow{\varphi} V \xrightarrow{\psi} k^m$ we can “repackage” the data of this structured span as an indexed family of affine varieties

$$V_{xy} := \varphi^{-1}(\mathbf{x}) \cap \psi^{-1}(\mathbf{y}) \quad (39)$$

each of which is a subvariety of V .

In the particular case where $k = \mathbb{F}_q$ is a finite field, and V is an $\mathbb{F}_q$ -rational locus, the family of affine varieties V_{xy} consists of finite sets, which we can view as entried in an $\mathbb{N}$ -matrix:

Definition 6.11. Let $M_q : {}_{G_q} \text{Span}(\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)}) \rightarrow \text{Mat}_{\mathbb{N}}$ be the functor which sends a structured span of $\mathbb{F}_q$ -rational loci

$$\mathbb{F}_q^n \xleftarrow{\varphi} V \xrightarrow{\psi} \mathbb{F}_q^m \quad (40)$$

to the $q^n \times q^m$ -matrix $M_q(\xleftarrow{\varphi} \xrightarrow{\psi})$ with entries

$$M_q(\xleftarrow{\varphi} \xrightarrow{\psi})_{xy} = |\varphi^{-1}(\mathbf{x}) \cap \psi^{-1}(\mathbf{y})|. \quad (41)$$

The following is immediate (proofs are given in C.2):

Proposition 6.12. *The functor M_q is well-defined and fully faithful.*

Since $\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)} \simeq \text{FinSet}$, this is just a restriction of the equivalence, well-known in folklore, between $\text{Span}(\text{FinSet}) \simeq \text{Mat}_{\mathbb{N}}$ in disguise.

But since we already know that $\mathbb{L}_{\text{Span}_q}$ is a sound, universal, and complete language for ${}_{G_q} \text{Span}(\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)})$ from section 6.2, so:

Corollary 6.13. *The diagrammatic language $\mathbb{L}_{\text{Span}_q}$ serves as a sound, universal, and complete language for a full subcategory of $\text{Mat}_{\mathbb{N}}$ consisting of the objects q^n with $n \in \mathbb{N}$.*

We use $\llbracket - \rrbracket_q : \mathbb{L}_{\text{Span}_q} \rightarrow \text{Mat}_{\mathbb{N}}$ to denote this new semantic.

7 From GAG to Counting CSP

We now briefly illustrate the direct connection between GAG and CSP. Recall that a constraint satisfaction problem over a domain D and a constraint language Γ (typically a set of finite arity relations over D) is a pair $\langle X, C \rangle$, where:

- X is a set of variables $x_1, \dots, x_n$,
- $C = \{C_1, \dots, C_m\}$ is a set of constraints, each of which is a pair $C_j = \langle s_j, g_j \rangle$ where $s_j \subset X$ is the scope of the constraint, and $g_j \in \Gamma$ is the content of the constraint.

An assignment $\sigma : X \rightarrow D$ is said to satisfy the CSP if for every j , the tuple $(\sigma(x_i))_{i \in s_j}$ is in the relation g_j . The problem of determining whether there exists an assignment σ that satisfies $\langle X, C \rangle$ is called the decision problem $\text{CSP}(\Gamma)$; while the problem of counting the number of assignments that satisfy $\langle X, C \rangle$ is called the counting problem $\#\text{CSP}(\Gamma)$.

Now suppose that our domain of values is a finite field $\mathbb{F}_q$, and our constraint language Γ consists of polynomial maps $g : \mathbb{F}_q^n \rightarrow \mathbb{F}_q$, read as the requirement $g = 0$. Of course, every finite-arity relation over $\mathbb{F}_q$ can be expressed as an affine variety, and therefore our Γ is just the set of all relations over D . The finite field GAG gives an easy representation of instances of $\#\text{CSP}(\Gamma)$ in the following way:

Proposition 7.1. *Let $\langle X, C \rangle$ be a CSP instance over the domain $\mathbb{F}_q$, with set of variables $X = \{x_1, \dots, x_n\}$, and polynomial constraints $g_1, \dots, g_m \in k[x_1, \dots, x_n]$. Let I be the ideal generated by $g_1, \dots, g_m$. Then the span semantic of the ideal gadget is*

$$n \xrightarrow{\triangle} n \xrightarrow{\llbracket - \rrbracket_q} \left(\mathbb{F}_q^n \xleftrightarrow{V(I)^{\mathbb{F}_q}} \mathbb{F}_q^n \right) \quad (42)$$

where, recall, $V(I)^{\mathbb{F}_q} := \{\mathbf{x} \in \mathbb{F}_q^n : g_1(\mathbf{x}) = \dots = g_m(\mathbf{x}) = 0\}$. In other words, it is the set of assignments satisfying $\langle X, C \rangle$.

The same diagram with no wires on either side has the following matrix semantic:

$$\triangle \xrightarrow{\llbracket - \rrbracket_q} |V(I)^{\mathbb{F}_q}| \quad (43)$$

In other words, it is the number of assignments that satisfy $\langle X, C \rangle$.

Theorem 7.2. *The problem of rewriting arbitrary GAG diagrams into each other is #P-hard.*

PROOF. This is a direct consequence of equation 43 in proposition 7.1, which shows that $\#\text{CSP}(\Gamma)$ reduces to rewriting between a subset of diagrams in GAG, and $\#\text{CSP}(\Gamma)$ is #P-complete [41]. $\square$

Remark 7.3. In the case $q = 2$, polynomial constraints are equivalent to boolean constraints, and so $\#\text{CSP}(\Gamma)$ is #SAT.

Remark 7.4. Conversely, since every diagram in GAG can be rewritten into cospan form, so every *closed* diagram (a diagram without input or output wires) can be rewritten into:

$$\begin{array}{c} \triangle \\ \text{---} \end{array} \xrightarrow{\text{(POLY-DEL)}} \begin{array}{c} \triangle \\ \text{---} \end{array} \xrightarrow{\text{(Z-FUSION)}} \begin{array}{c} \triangle \\ \text{---} \end{array} \quad (44)$$

So determining the semantic of an arbitrary *closed* diagram in GAG is equivalent to $\#CSP(\Gamma)$.

8 From GAG to Qudit ZH Calculus

The ZH calculus is a graphical language for quantum computation, and it has a natural correspondence with the Toffoli-Hadamard gate set. In this section, we elucidate the connection between algebraic geometry and the ZH calculus. We review the Galois-Qudit ZH calculus introduced in [28] and show that the ZH calculus can be obtained as a fairly minimal extension of finite-field GAG: adding a single state and one scalar suffices to recover the ZH calculus in arbitrary dimension.

8.1 Qudit ZH Calculus

Here we give a brief overview of the qudit ZH Calculus as introduced in [28].

Definition 8.1. [45] A Galois-Qudit is a quantum system represented by a Hilbert space of dimension $q = p^t$ for some prime p and some natural number t , with a computational basis labelled as $|j\rangle$ with $j \in \mathbb{F}_q$.

For a finite field $\mathbb{F}_q$, the **Galois-Qudit ZH Calculus** over $\mathbb{F}_q$ is the free² dagger-PROP generated by three families of generators:

$$\begin{array}{ccc} \begin{array}{c} n \vdots \\ \text{---} \\ m \vdots \end{array} & \begin{array}{c} n \vdots \\ \text{---} \\ m \vdots \end{array} & \begin{array}{c} j \\ \text{---} \end{array} \\ \text{Z spider} & \text{H spider} & j\text{-state} \end{array}$$

We will denote this free dagger-PROP as ZH. It admits a semantics functor to the PROP $q^{\frac{1}{2}} \text{Mat}_{\mathbb{Z}[\omega]}$. A morphism from n to m in $q^{\frac{1}{2}} \text{Mat}_{\mathbb{Z}[\omega]}$ is a matrix of the form $q^{\frac{k}{2}} A$, where A is a $q^m \times q^n$ matrix with entries in the ring $\mathbb{Z}[\omega]$, ω is a primitive p th root of 1, and k is an integer.

$$\text{ZH} \xrightarrow{[\![\cdot]\!]}_{\text{ZH}} q^{\frac{1}{2}} \text{Mat}_{\mathbb{Z}[\omega]} \quad (45)$$

This functor is full [28] and is defined on the generators as follows:

$$\begin{array}{ccc} \begin{array}{c} n \vdots \\ \text{---} \\ m \vdots \end{array} & \mapsto & \sum_{i \in \mathbb{F}_q} |i\rangle^{\otimes m} \langle i|^{\otimes n} \\ \begin{array}{c} n \vdots \\ \text{---} \\ m \vdots \end{array} & \mapsto & \frac{1}{\sqrt{q}} \sum_{\substack{j_1, \dots, j_m \in \mathbb{F}_q \\ i_1, \dots, i_n \in \mathbb{F}_q}} \omega^{\text{tr}(j_1 \dots j_m i_1 \dots i_n)} |j_1\rangle \dots |j_m\rangle \langle i_1| \dots \langle i_n| \\ \begin{array}{c} j \\ \text{---} \end{array} & \mapsto & \sqrt{q} |j\rangle \quad j \in \mathbb{F}_q \end{array}$$

where $\text{tr}(x) = x^p + \dots + x^{p^{t-1}}$ is the field trace polynomial, which maps $\mathbb{F}_q \rightarrow \mathbb{F}_p$ linearly over $\mathbb{F}_p$.

²No complete set of rewrite rules are known for the qudit ZH. For the sake of full generality, we work with the free dagger-PROP generated by the ZH generators.

8.2 ZH Calculus as an Extension of GAG

We now extend the language $\mathbb{L}_{\text{Span}_q}$ for finite field GAG to cover the entirety of the Galois-Qudit ZH Calculus over $\mathbb{F}_q$.

Definition 8.2. Define $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$ to be the PROP generated by $\mathbb{L}_{\text{Span}_q}$ together with the following additional generators

$$\begin{array}{c} 1 \\ \text{---} \end{array} \quad \boxed{q^{-\frac{1}{2}}} \quad (46)$$

and the following additional rewrite rules

$$\begin{array}{ccc} \begin{array}{c} 1 \\ \text{---} \end{array} & \xrightarrow{\text{(Z1-COPY)}} & \begin{array}{c} 1 \\ \text{---} \end{array} \\ \begin{array}{c} 1 \\ \text{---} \end{array} & \xrightarrow{\text{(Z1-TRACE)}} & \begin{array}{c} 1 \\ \text{---} \end{array} \\ \begin{array}{c} 1 \\ \text{---} \end{array} & \xrightarrow{\text{(Z1-CHANGE)}} & \begin{array}{c} 1 \\ \text{---} \end{array} \end{array} \quad (47)$$

Where tr is the field trace polynomial and ξ is any element of $\mathbb{F}_q$ with $\text{tr} \xi = 1$. Here, we think of $\begin{array}{c} 1 \\ \text{---} \end{array}$ as a state in the Fourier basis as we define below.

Definition 8.3. We define the semantic functor $[\![\cdot]\!]_q^{\text{Fourier}} : \mathbb{L}_{\text{Span}_q}^{\text{Fourier}} \rightarrow q^{\frac{1}{2}} \text{Mat}_{\mathbb{Z}[\omega]}$. For each generator of $\mathbb{L}_{\text{Span}_q}$, we set $[\![\cdot]\!]_q^{\text{Fourier}}$ to be the composition of $[\![\cdot]\!]_q$ with the canonical inclusion $\text{Mat}_{\mathbb{N}} \hookrightarrow q^{\frac{1}{2}} \text{Mat}_{\mathbb{Z}[\omega]}$. For the additional generators, we define:

$$[\![\begin{array}{c} 1 \\ \text{---} \end{array}]\!]_q^{\text{Fourier}} = \sum_{i \in \mathbb{F}_q} \omega^{\text{tr}(i)} |i\rangle \quad (48)$$

$$[\![\boxed{q^{-\frac{1}{2}}}\!]\!]_q^{\text{Fourier}} = q^{-\frac{1}{2}} \quad (49)$$

This forces the following to commute:

$$\begin{array}{ccc} \mathbb{L}_{\text{Span}_q}^{\text{Fourier}} & \xrightarrow{[\![\cdot]\!]_q^{\text{Fourier}}} & q^{\frac{1}{2}} \text{Mat}_{\mathbb{Z}[\omega]} \\ \uparrow & & \uparrow \\ \mathbb{L}_{\text{Span}_q} & \xrightarrow{[\![\cdot]\!]_q} & \text{Mat}_{\mathbb{N}} \end{array}$$

Moreover:

Proposition 8.4. The rewrite rules in equation (47) are sound with respect to the semantics $[\![\cdot]\!]_q^{\text{Fourier}}$.

The dagger-PROP $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$ covers the entirety of the Galois-Qudit ZH Calculus. To see this, we describe how its generators can be constructed in $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$ and show that the semantics agree.

Definition 8.5. We have the functor $\iota_{\text{ZH}} : \text{ZH} \rightarrow \mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$ defined on the generators as follows:

$$\begin{array}{ccc} \begin{array}{c} n \vdots \\ \text{---} \\ m \vdots \end{array} & \mapsto & \begin{array}{c} n \vdots \\ \text{---} \\ m \vdots \end{array} \\ \begin{array}{c} n \vdots \\ \text{---} \\ m \vdots \end{array} & \mapsto & \begin{array}{c} \boxed{q^{-\frac{1}{2}}} \\ \text{---} \\ n \vdots \end{array} \\ \begin{array}{c} j \\ \text{---} \end{array} & \mapsto & \begin{array}{c} \text{---} \\ \text{---} \\ \boxed{q^{-\frac{1}{2}}} \end{array} \end{array}$$

Proposition 8.6. *The functor ι_{ZH} is consistent with the semantics of the ZH Calculus. In other words, the following diagram commutes:*

$$\begin{array}{ccc} \mathbb{L}_{\text{Span}_q}^{\text{Fourier}} & \xrightarrow{\llbracket - \rrbracket_q^{\text{Fourier}}} & q^{\frac{1}{2}} \text{Mat}_{\mathbb{Z}[\omega]} \\ \uparrow \iota_{\text{ZH}} & \nearrow \llbracket - \rrbracket_{\text{ZH}} & \\ \text{ZH} & & \end{array}$$

For the remainder of this paper we will use $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$ as a working notion of a Galois-Qudit ZH calculus with rewrite rules – we will show that the rewrite rules of $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$ forms a complete set of rules for ZH. Now, we show just how minimal an extension $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$ is over $\mathbb{L}_{\text{Span}_q}$:

Proposition 8.7. *For any diagram D in $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$, there exists $k \in \mathbb{N}$ and a diagram D' containing only the generators of $\mathbb{L}_{\text{Span}_q}$ such that*

$$\begin{array}{c} \vdots \\ \boxed{D} \\ \vdots \end{array} = \begin{array}{c} \vdots \\ \boxed{D'} \\ \vdots \end{array} \quad (50)$$

$\begin{array}{c} \textcircled{1} \\ q^{-\frac{1}{2}} \end{array} (\otimes k)$

This shows that just a single copy of the state in the fourier basis is sufficient to extend the expressive power of finite-field GAG to cover the entirety of the Galois-Qudit ZH Calculus. Using this, we can compute amplitudes in the ZH calculus using finite-field GAG. Computing an amplitude in the ZH calculus corresponds to evaluating the semantics of a scalar diagram. We have the following result.

Theorem 8.8. *Let D be a scalar diagram in the ZH calculus over $\mathbb{F}_q$. The scalar $\llbracket D \rrbracket_{\text{ZH}}$ can be computed using exactly q queries to an oracle O that evaluates the semantics of scalar diagrams in $\mathbb{L}_{\text{Span}_q}$.*

9 Catalyzing Qudit ZH Completeness

Theorem 9.1 (Completeness of Galois-Qudit ZH). *If D_1, D_2 are diagrams in the Galois-Qudit ZH Calculus over $\mathbb{F}_q$, and $\llbracket D_1 \rrbracket_{\text{ZH}} = \llbracket D_2 \rrbracket_{\text{ZH}}$, then D_1 can be rewritten into D_2 using the rewrite rules of $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$.*

The first thing to notice is that to prove theorem 9.1, it suffices to prove it for states (diagrams without inputs) because any diagram, composed with cups, can be turned into a state, and vice-versa. Notice also that proposition 8.7 implies that a state in the ZH calculus can be rewritten into the form

$$\begin{array}{c} \vdots \\ \boxed{D} \\ \vdots \end{array} = \begin{array}{c} \vdots \\ \boxed{D'} \\ \vdots \end{array} \quad (51)$$

$\begin{array}{c} \textcircled{1} \\ q^{-\frac{1}{2}} \end{array} (\otimes k)$

where D' is a diagram in the language $\mathbb{L}_{\text{Span}_q}$.

Our proof uses a catalysis-style argument [47]. We have a larger language (the Galois-qudit ZH) which extends a smaller language (the language $\mathbb{L}_{\text{Span}_q}$ of finite field GAG), in such a way that any diagram in ZH can be rewritten as a diagram in $\mathbb{L}_{\text{Span}_q}$, with some gadgets attached. Catalysis is about reducing the ZH semantic equality of D_1, D_2 to some form semantic equality statement between diagrams of $\mathbb{L}_{\text{Span}_q}$, involving subdiagrams of D_1, D_2 . This allows

us to leverage our knowledge that $\mathbb{L}_{\text{Span}_q}$ is complete for $\text{Mat}_{\mathbb{N}}$ semantics, to derive the desired rewrites for D_1 and D_2 in ZH. In our case, the catalysis reduction is as follows:

Proposition 9.2. *If*

$$\boxed{D_1} \vdash \begin{array}{c} n \\ 1 \end{array} \quad \text{and} \quad \boxed{D_2} \vdash \begin{array}{c} n \\ 1 \end{array}$$

are diagrams in $\mathbb{L}_{\text{Span}_q}$, such that

$$\left[\boxed{D_1} \textcircled{1} \right]_{\text{ZH}} = \left[\boxed{D_2} \textcircled{1} \right]_{\text{ZH}} \quad (52)$$

and satisfying the following restriction condition: for all $x \in \mathbb{F}_q$ except for those lying on one line $\xi \mathbb{F}_p$ where ξ is some fixed element of field trace 1,

$$\left[\boxed{D_1} \textcircled{x} \right]_{\text{ZH}} = \left[\boxed{D_2} \textcircled{x} \right]_{\text{ZH}} = 0 \quad (53)$$

Then there exist diagrams $\boxed{C_1} \vdash n, \boxed{C_2} \vdash n$ in $\mathbb{L}_{\text{Span}_q}$ such that

$$\left[\boxed{D_1} \right]_q + \left[\boxed{C_1} \textcircled{\circ} \right]_q = \left[\boxed{D_2} \right]_q + \left[\boxed{C_2} \textcircled{\circ} \right]_q \quad (54)$$

Notice that a semantic equality in ZH results not in an exact semantic equality in graphical algebraic geometry, but in an equality of sums. Luckily graphical algebraic geometry supplies the necessary gadgets for diagrammatically computing sums. This involves constructing so-called controlled-states for various diagrams in $\mathbb{L}_{\text{Span}_q}$, and then using those to construct sums.

Lemma 9.3. *Let $\tilde{Z}$ be the following diagram in $\mathbb{L}_{\text{Span}_q}$:*

$$\boxed{\tilde{Z}} := \text{---} \xrightarrow{1-xq^{-1}} \text{---} \quad (55)$$

Then the following rewrites hold in $\mathbb{L}_{\text{Span}_q}$:

$$\text{---} \boxed{\tilde{Z}} \text{---} = \text{---} \quad \text{---} \boxed{\tilde{Z}} \text{---} = \text{---} \quad (56)$$

meaning that $\tilde{Z}$ serves as a controlled version of $\text{---} \textcircled{\circ} \text{---}$; and moreover the following rewrite holds in $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$:

$$\boxed{\tilde{Z}} \textcircled{1} = \text{---} \quad (57)$$

Now for any state $\boxed{\psi} \vdash n$ in $\mathbb{L}_{\text{Span}_q}$, recalling the (co)span normal form of graphical algebraic geometry (see (30)), ψ can be rewritten into the form

$$\boxed{\Psi} = \text{---} \textcircled{\circ} \text{---} \text{---} \text{---} \quad (58)$$

Lemma 9.4. *For any state $\boxed{\Psi} = \text{---} \textcircled{\circ} \text{---} \text{---} \text{---}$ in $\mathbb{L}_{\text{Span}_q}$, there is a diagram $1 \text{---} \boxed{\tilde{\Psi}} \text{---} n$ (the so-called controlled state of ψ) such that the following are rewriteable in $\mathbb{L}_{\text{Span}_q}$:*

$$\text{---} \boxed{\tilde{\Psi}} \text{---} = \text{---} \quad ; \quad \text{---} \boxed{\tilde{\Psi}} \text{---} = \boxed{\Psi} \text{---} \quad (59)$$

Explicitly, $\tilde{\Psi}$ is constructed as

$$1 \text{---} \boxed{\tilde{\Psi}} \text{---} n := \text{---} \text{---} \quad (60)$$

Proposition 9.5. For any states $\boxed{\psi} \vdash n, \boxed{\Phi} \vdash n$ in $\mathbb{L}_{\text{Span}_q}$, let $\tilde{\psi}, \tilde{\phi}$ be their corresponding controlled states as defined in (60). Then the following diagram has the sum of ψ and ϕ as its semantics:

$$\left[\begin{array}{c} \boxed{\tilde{\Psi}} \\ \boxed{\tilde{\Phi}} \end{array} \right]_q = \left[\boxed{\Psi} \right]_q + \left[\boxed{\Phi} \right]_q \quad (61)$$

Now we return to the particular form of sums occurring in equation (70). Recall that in that sum, the second terms involve the factor $\bigcirc \text{---} 1$. Notice that

$$\left[\bigcirc \text{---} 1 \right]_q = \sum_{\theta \in \mathbb{F}_p} \omega^\theta = 0 \quad (62)$$

And so we might ask: are the rewrites of $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$ enough to detect that a sum of the form in equation (70) would lose its second term when plugged together with a $\bigcirc \text{---} 1$? It turns out that this work is done by equation (57), which yields the following stronger form of proposition 9.5

Proposition 9.6. For diagrams $\boxed{D} \vdash n, \boxed{C} \vdash n$ in $\mathbb{L}_{\text{Span}_q}$, letting

$$\boxed{D+C} := \left[\begin{array}{c} \boxed{\tilde{D}} \\ \boxed{\tilde{C}} \\ \boxed{\tilde{Z}} \end{array} \right] \quad (63)$$

where $\tilde{D}, \tilde{C}, \tilde{Z}$ are the corresponding controlled diagrams, then the following semantic equality of sums holds:

$$\left[\boxed{D+C} \right]_q = \left[\boxed{D} \right]_q + \left[\boxed{C} \text{---} \bigcirc \right]_q \quad (64)$$

and moreover, the following rewrite holds in the language $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$:

$$\boxed{D+C} \text{---} 1 = \boxed{D} \text{---} 1 \quad (65)$$

Which yields a catalysis argument for the completeness of the Galois-Qudit ZH Calculus up to global scalars:

Proposition 9.7. If

$$\boxed{D_1} \vdash \frac{n}{1} \quad \boxed{D_2} \vdash \frac{n}{1}$$

are diagrams in $\mathbb{L}_{\text{Span}_q}$ such that

$$\left[\boxed{D_1} \text{---} 1 \right]_{\text{ZH}} = \left[\boxed{D_2} \text{---} 1 \right]_{\text{ZH}} \quad (66)$$

then the following holds in $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$:

$$\boxed{D_1} \text{---} 1 = \boxed{D_2} \text{---} 1 \quad (67)$$

PROOF OF PROPOSITION 9.7. First, since using rule (Z1-TRACE) we can rewrite

$$\boxed{D_1} \text{---} 1 = \boxed{D_1} \text{---} \text{tr} \text{---} \xi \text{---} 1 \quad (68)$$

and it is easy to check, seeing as $\text{tr}(\mathbb{F}_q) = \mathbb{F}_p$, that

$$\left[\boxed{D_1} \text{---} \text{tr} \text{---} \xi \text{---} \bigcirc \right]_q = 0 \quad (69)$$

for any $x \notin \xi \mathbb{F}_p$. So, without loss of generality we may assume that D_1 satisfies the restriction condition (53). Similarly, the condition also holds for D_2 .

Proposition 9.2 then tells us that there exist diagrams $\boxed{C_1} \vdash$, $\boxed{C_2} \vdash$ in $\mathbb{L}_{\text{Span}_q}$ such that

$$\left[\boxed{D_1} \right]_q + \left[\boxed{C_1} \text{---} \bigcirc \right]_q = \left[\boxed{D_2} \right]_q + \left[\boxed{C_2} \text{---} \bigcirc \right]_q \quad (70)$$

Then constructing D_{1+C_1}, D_{2+C_2} as in Proposition 9.6, we obtain diagrams in $\mathbb{L}_{\text{Span}_q}$ such that

$$\begin{aligned} \left[\boxed{D_{1+C_1}} \right]_q &= \left[\boxed{D_1} \right]_q + \left[\boxed{C_1} \text{---} \bigcirc \right]_q \\ &= \left[\boxed{D_2} \right]_q + \left[\boxed{C_2} \text{---} \bigcirc \right]_q \\ &= \left[\boxed{D_{2+C_2}} \right]_q \end{aligned} \quad (71)$$

So by the completeness of graphical algebraic geometry (Proposition 6.9) we have rewrites in $\mathbb{L}_{\text{Span}_q}$:

$$\boxed{D_{1+C_1}} \stackrel{6.9}{=} \boxed{D_{2+C_2}} \quad (72)$$

But then by the rewrite (65) given in proposition 9.6, we have rewrites

$$\boxed{D_1} \text{---} 1 \stackrel{(65)}{=} \boxed{D_{1+C_1}} \text{---} 1 \stackrel{6.9}{=} \boxed{D_{2+C_2}} \text{---} 1 \stackrel{(65)}{=} \boxed{D_2} \text{---} 1 \quad (73)$$

□

10 Conclusion and Future Directions

We have introduced a family of diagrammatic languages, which we refer to collectively as graphical algebraic geometry (GAG). This family of languages extends the existing literature on graphical linear algebra (GLA) by introducing the nonlinear multiplication operator. We construct three examples of languages within this family, and show that they are sound, universal, and complete, for their respective semantics in (co)spans of commutative algebras and affine varieties.

We showed that closed diagrams in GAG correspond exactly to counting constraint satisfaction problems, thereby showing that rewriting GAG diagrams into each other is #P-hard. We show also that GAG forms the nonlinear classical “backbone” of the Galois-qudit ZH calculus. Indeed, we show that all quantum processes in the qudit ZH calculus can be represented by consuming a single Fourier basis state, up to a finite number of scalars, meaning that a GAG oracle would be able to simulate the ZH processes with a constant number of queries. These connections serve to illustrate the potential versatility of GAG.

There are several directions of future work. On the theoretic side, there is an open question of constructing graphical algebraic geometry over $\mathbb{R}$. Indeed, for a real-closed field, one would be able to express inequality constraints of the form $g(x) \geq 0$ using the generators of GAG; but finding a complete set of rewrite rules for such languages may prove difficult, and will involve the Positivstellensatz. Such a language would have exciting applications in the verification of hybrid systems, where the safety space is often given as a semialgebraic set in $\mathbb{R}^n$, and dynamics are given by polynomial mappings [60]. On the practical side, there are two obvious

directions. The first is to explore the connection between GAG and CSP: in particular, are their existing computational techniques that can optimize GAG rewriting, or bound the complexity of rewriting between diagrams of a certain class? The second is to use the characterization of ZH as an extension of GAG to “grok” quantum algebraic geometry codes, in the same way graphical linear algebra has been used to “grok” CSS codes [46].

A Derived Rules for Scalable Notation in $\mathbb{L}_{\text{CAlg}_k}$

Proposition 3.3. *From the rewrite rules of $\mathbb{L}_{\text{CAlg}_k}$ it is possible to derive the rewrite rules about polynomials in the scalable notation, as depicted in figure 4.*

PROOF. We begin by proving that rewrite rule (POLY-COPY) is derivable in $\mathbb{L}_{\text{CAlg}_k}$, that is,

$$\text{---} \overline{\text{f}} \text{---} \bigcirc \text{---} = \text{---} \bigcirc \text{---} \begin{matrix} \text{f} \\ \text{f} \end{matrix} \quad (74)$$

Since by theorem 3.2 the polynomials are in correspondence with diagrams in $\mathbb{L}_{\text{CAlg}_k}$, so we may prove this proposition by structural induction on diagrams.

First we check that the equation holds the generators. The equation is immediate if $\text{---} \overline{\text{f}} \text{---} = \text{---} \bigcirc \text{---}$.

If $\text{---} \overline{\text{f}} \text{---} = \text{---} \bigcirc \text{---}$, then we have:

$$\begin{aligned} \text{LHS} &= \text{---} \bigcirc \text{---} \begin{matrix} \text{f} \\ \text{f} \end{matrix} \\ &\stackrel{(\text{Z-ASSOC})}{=} \text{---} \bigcirc \text{---} \begin{matrix} \text{f} \\ \text{f} \end{matrix} \\ &\stackrel{(\text{Z-ASSOC})}{=} \text{---} \bigcirc \text{---} \begin{matrix} \text{f} \\ \text{f} \end{matrix} \\ &\stackrel{(\text{Z-SYMM})}{=} \text{---} \bigcirc \text{---} \begin{matrix} \text{f} \\ \text{f} \end{matrix} \\ &\stackrel{(\text{Z-ASSOC})}{=} \text{---} \bigcirc \text{---} \begin{matrix} \text{f} \\ \text{f} \end{matrix} = \text{RHS} \end{aligned} \quad (75)$$

If $\text{---} \overline{\text{f}} \text{---} = \text{---} \bigcirc \text{---}$, then we have (recalling that the spider with legs labelled by 0 is the empty diagram):

$$\text{LHS} = \text{---} \bigcirc \text{---} \stackrel{(\text{Z-UNIT})}{=} \text{---} \bigcirc \text{---} = \text{RHS} \quad (76)$$

If $\text{---} \overline{\text{f}} \text{---} = \text{---} \bigcirc \text{---}$, then we have:

$$\text{LHS} = \text{---} \bigcirc \text{---} \stackrel{(\text{ADD-CP})}{=} \text{---} \bigcirc \text{---} = \text{RHS} \quad (77)$$

If $\text{---} \overline{\text{f}} \text{---} = \text{---} \bigcirc \text{---}$, then we have:

$$\text{LHS} = \text{---} \bigcirc \text{---} \stackrel{(\text{ZERO-CP})}{=} \text{---} \bigcirc \text{---} = \text{RHS} \quad (78)$$

If $\text{---} \overline{\text{f}} \text{---} = \text{---} \bigcirc \text{---}$, then we have:

$$\text{LHS} = \text{---} \bigcirc \text{---} \stackrel{(\text{MULT-CP})}{=} \text{---} \bigcirc \text{---} = \text{RHS} \quad (79)$$

If $\text{---} \overline{\text{f}} \text{---} = \text{---} \bigcirc \text{---}$, then we have:

$$\text{LHS} = \text{---} \bigcirc \text{---} \stackrel{(\text{ONE-CP})}{=} \text{---} \bigcirc \text{---} = \text{RHS} \quad (80)$$

If $\text{---}\Sigma f\text{---} = \text{---}\Box K\text{---}$, then we have:

$$LHS = \text{---} \boxed{k} \text{---} \bigcirc \text{---} \text{---} \stackrel{(\text{K-COPY})}{=} \text{---} \bigcirc \text{---} \begin{matrix} \boxed{k} \text{---} \\ \boxed{k} \text{---} \end{matrix} = RHS \quad (81)$$

Thus the proposition holds for all the generators of $\mathbb{L}_{\text{CAlg}k}$. Now for the inductive step: suppose the proposition holds for $n \xrightarrow{\text{--}\mathcal{F}\text{--}} m$ and $n' \xrightarrow{\text{--}\mathcal{G}\text{--}} m'$. Then, in the case $m = n'$, consider the diagram $\xrightarrow{\text{--}\mathcal{F}\text{--}} \xrightarrow{\text{--}\mathcal{G}\text{--}}$. we have

$$\begin{aligned}
LHS &= \text{diagram with incoming line, } f \text{ box, } g \text{ box, and outgoing line} \\
&\stackrel{\text{I.H.}}{=} \text{diagram with } f \text{ box, } g \text{ box, and two outgoing lines} \\
&\stackrel{\text{I.H.}}{=} \text{diagram with } f \text{ box, } g \text{ box, and two outgoing lines} = RHS
\end{aligned} \tag{82}$$

Finally, for the diagram we have

$$LHS = \text{Diagram 1} \stackrel{\text{I.H.}}{=} \text{Diagram 2} = RHS \quad (83)$$

Here, I.H. denotes the inductive hypothesis. This completes the induction.

We next prove that rule (POLY-DEL) is deriveable in $\mathbb{L}_{\text{CALQ}_k}$, that is,

$$\rightarrow \text{[wavy line with } f \text{]} \rightarrow \text{[circle]} = \text{[line]} \rightarrow \text{[circle]} \quad (84)$$

We again use structural induction on the diagrams of $\mathbb{L}_{CAlg_k}$. The equation is tautological if either $\text{---}\overline{\text{---}}\text{---} = \text{---}$ or $\text{---}\overline{\text{---}}\text{---} = \text{---}\bigcirc$ (recalling that the spider with legs labelled by 0 is the empty diagram).

If $\text{---}\langle f \rangle\text{---} = \text{---}\circ\text{---}$, we have

$$LHS = \text{---} \bigcirc \begin{matrix} \nearrow \bigcirc \\ \searrow \bigcirc \end{matrix} \stackrel{(z\text{-UNIT})}{=} \text{---} \bigcirc = RHS \quad (85)$$

If $\dashv\!\!\!\dashv =$  or  or  or  or , the desired proposition is just a straightforward application of axioms (ADD-DEL), (ZERO-DEL), (MULT-DEL), (ONE-DEL), (K-DEL) respectively. So the proposition holds for all generators of $\mathcal{L}_{\text{CALgk}}$. Now for the inductive step: suppose the proposition holds for $n \dashv\!\!\!\dashv m$ and $n' \dashv\!\!\!\dashv m'$. Then, in the case $m = n'$, consider the diagram $\dashv\!\!\!\dashv \dashv\!\!\!\dashv$. we have

$$LHS = \text{---} \text{f} \text{---} \text{g} \text{---} \bigcirc \stackrel{\text{I.H.}}{=} \text{---} \text{f} \text{---} \bigcirc \stackrel{\text{I.H.}}{=} \text{---} \bigcirc = RHS \quad (86)$$

Finally, for the diagram  we have

$$LHS = \begin{array}{c} \text{---}\overline{\Sigma f}\text{---}\bigcirc \\ \text{---}\overline{\Sigma g}\text{---}\bigcirc \end{array} \stackrel{\text{I.H.}}{=} \begin{array}{c} \text{---}\bigcirc \\ \text{---}\bigcirc \end{array} = RHS \quad (87)$$

This completes the induction. $\square$

Finally, the rules (POLY-ADD) , (POLY-MULT) , and (POLY-COMP) are direct consequences of the fact that $\mathbb{L}_{\text{CALg}_k}$ is the Lawvere theory of commutative algebras over k . $\square$

B Proofs about $\mathbb{L}_{\text{Cosp}}$

B.1 Proofs about Soundness

Proposition 5.2 (Cospan Soundness). *Every rewrite rule in E is sound with respect to the intended semantic $[-]$.*

PROOF. First to prove $(K-INV)$: for $l \in k^\times$,

$$\begin{aligned}
[\text{---} \boxed{D} \text{---}] &= \left(k[x] = k[x] \xleftarrow{y \mapsto l x} k[y] \right) \\
&= \left(k[x] \xrightarrow{x \mapsto l^{-1} y} k[y] = k[y] \right) \\
&= [\text{---} \boxed{l^{-1}} \text{---}]
\end{aligned} \tag{88}$$

where the second equality is the span isomorphism

$$\begin{array}{ccccc}
 & & k[x] & & \\
 & \swarrow & \downarrow & \nwarrow l_x & \\
 k[x] & & l^{-1}y & & k[y] \\
 & \searrow & \downarrow & \swarrow & \\
 & & k[y] & &
 \end{array}$$

Next to prove (X-BONE):

$$\begin{aligned} [\text{---}\bigcirc\text{---}\bigcirc] &= \left(k = k \xleftarrow{x^1 \mapsto 0} k[x] \xrightarrow{x^1 \mapsto 0} k = k \right) \\ &= (k = k = k) = \left[\begin{array}{c} \text{---} \end{array} \right] \end{aligned} \quad (89)$$

here the second equality is the pushout

$$\begin{array}{ccc}
 & k & \\
 \swarrow & \checkmark & \searrow \\
 k & & k \\
 \nwarrow & & \nearrow \\
 & k[x] & \\
 \text{\scriptsize } x \mapsto 0 & & \text{\scriptsize } x \mapsto 0
 \end{array}$$

Next to prove_(Z-FROB):

$$\begin{aligned}
& \left[\text{Diagram: A box containing two nodes. The top node has two incoming lines from the left and one outgoing line to the bottom node. The bottom node has one incoming line from the left and one outgoing line to the right.} \right] \\
&= \left(k[x_1, x_2] \xleftarrow{\begin{smallmatrix} x_1 \leftarrow y_1 \\ x_1 \leftarrow y_2 \\ x_2 \leftarrow y_3 \end{smallmatrix}} k[y_1, y_2, y_3] \xrightarrow{\begin{smallmatrix} y_1 \mapsto z_1 \\ y_2 \mapsto z_2 \\ y_3 \mapsto z_2 \end{smallmatrix}} k[z_1, z_2] \right) \\
&= \left(k[x_1, x_2] \rightarrow \frac{k[x_1, x_2, z_1, z_2]}{(x_1 - z_1, x_1 - z_2, x_2 - z_2)} \leftarrow k[z_1, z_2] \right) \\
&= \left(k[x_1, x_2] \xrightarrow{\begin{smallmatrix} x_1 \mapsto y \\ x_2 \mapsto y \end{smallmatrix}} k[y] \xleftarrow{\begin{smallmatrix} y \leftarrow z_1 \\ y \leftarrow z_2 \end{smallmatrix}} k[z_1, z_2] \right) = \left[\text{Diagram: A box containing two nodes. The top node has one incoming line from the left and one outgoing line to the bottom node. The bottom node has one incoming line from the left and one outgoing line to the right.} \right] \quad (90) \\
&= \left(k[x_1, x_2] \xleftarrow{\begin{smallmatrix} x_1 \leftarrow y_1 \\ x_2 \leftarrow y_2 \\ x_2 \leftarrow y_3 \end{smallmatrix}} k[y_1, y_2, y_3] \xrightarrow{\begin{smallmatrix} y_1 \mapsto z_1 \\ y_2 \mapsto z_1 \\ y_3 \mapsto z_2 \end{smallmatrix}} k[z_1, z_2] \right) \\
&= \left[\text{Diagram: A box containing two nodes. The top node has two incoming lines from the left and one outgoing line to the bottom node. The bottom node has one incoming line from the left and one outgoing line to the right.} \right]
\end{aligned}$$

Next for the soundness of $(x\text{-FROB})$: first, by a pushout we obtain that

$$\begin{aligned}
 & \left[\text{Diagram: A circle with two nodes connected by a line, with a loop on the left node.} \right] \\
 &= \left(k[x_1, x_2] \xleftarrow{x_1+x_2 \leftarrow y} k[y] \xrightarrow{y \mapsto z_1+z_2} k[z_1, z_2] \right) \\
 &= \left(k[x_1, x_2] \rightarrow \frac{k[x_1, x_2, z_1, z_2]}{(x_1 + x_2 - z_1 - z_2)} \leftarrow k[z_1, z_2] \right)
 \end{aligned} \tag{91}$$

Now consider the apex of the cospan in the final line of 91. We can parametrize it in two ways:

$$\begin{array}{ccc}
 & k[u_1, u_2, u_3] & \\
 \begin{array}{l} x_1 \mapsto u_1 + u_2 \\ x_2 \mapsto u_3 \end{array} \nearrow & \uparrow \alpha & \nwarrow \begin{array}{l} z_1 \mapsto u_1 \\ z_2 \mapsto u_2 + u_3 \end{array} \\
 k[x_1, x_2] & \xrightarrow{\frac{k[x_1, x_2, z_1, z_2]}{(x_1 + x_2 - z_1 - z_2)}} & k[z_1, z_2] \\
 \searrow \begin{array}{l} x_1 \mapsto v_1 \\ x_2 \mapsto v_2 + v_3 \end{array} & \downarrow \beta & \swarrow \begin{array}{l} z_1 \mapsto v_1 + v_2 \\ z_2 \mapsto v_3 \end{array} \\
 & k[v_1, v_2, v_3] &
 \end{array}$$

where α, β are the obvious maps that make the above diagram commute:

$$\alpha : \begin{array}{ll} x_1 \mapsto u_1 + u_2 & x_1 \mapsto v_1 \\ x_2 \mapsto u_3 & x_2 \mapsto v_2 + v_3 \\ z_1 \mapsto u_1 & z_1 \mapsto v_1 + v_2 \\ z_2 \mapsto u_2 + u_3 & z_2 \mapsto v_3 \end{array} \quad \beta : \tag{92}$$

Which are both isomorphisms of algebras. This gives:

$$\begin{aligned}
 & \left[\text{Diagram: A circle with two nodes connected by a line, with a loop on the left node.} \right] \\
 &= \left(k[x_1, x_2] \rightarrow \frac{k[x_1, x_2, z_1, z_2]}{(x_1 + x_2 - z_1 - z_2)} \leftarrow k[z_1, z_2] \right) \\
 &= \left(k[x_1, x_2] \xrightarrow{\begin{array}{l} x_1 \mapsto u_1 + u_2 \\ x_2 \mapsto u_3 \end{array}} k[u_1, u_2, u_3] \xleftarrow{\begin{array}{l} u_1 \leftarrow z_1 \\ u_2 + u_3 \leftarrow z_2 \end{array}} k[z_1, z_2] \right) \\
 &= \left[\text{Diagram: A circle with two nodes connected by a line, with a loop on the left node.} \right] \\
 &= \left(k[x_1, x_2] \xrightarrow{\begin{array}{l} x_1 \mapsto v_1 \\ x_2 \mapsto v_2 + v_3 \end{array}} k[v_1, v_2, v_3] \xleftarrow{\begin{array}{l} v_1 + v_2 \leftarrow z_1 \\ v_3 \leftarrow z_2 \end{array}} k[z_1, z_2] \right) \\
 &= \left[\text{Diagram: A circle with two nodes connected by a line, with a loop on the left node.} \right]
 \end{aligned} \tag{93}$$

Now for the soundness of (CUP) :

$$\begin{aligned}
 & \left[\text{Diagram: A circle with two nodes connected by a line, with a loop on the left node.} \right] \\
 &= \left(k \xleftarrow{0 \leftarrow x} k[x] \xrightarrow{x \mapsto y_1 - y_2} k[y_1, y_2] \right) \\
 &= \left(k \rightarrow \frac{k[y_1, y_2]}{(y_1 - y_2)} \leftarrow k[y_1, y_2] \right) \\
 &= \left(k \rightarrow k[x] \xleftarrow{\begin{array}{l} x \leftarrow y_1 \\ x \leftarrow y_2 \end{array}} k[y_1, y_2] \right) \\
 &= \left[\text{Diagram: A circle with two nodes connected by a line, with a loop on the left node.} \right]
 \end{aligned} \tag{94}$$

The proof for the soundness of (CAP) is almost identical:

$$\begin{aligned}
 & \left[\text{Diagram: A circle with two nodes connected by a line, with a loop on the left node.} \right] \\
 &= \left(k[x_1, x_2] \xleftarrow{x_1 - x_2 \leftarrow y} k[y] \xrightarrow{y \mapsto 0} k \right) \\
 &= \left(k[x_1, x_2] \rightarrow \frac{k[x_1, x_2]}{(x_1 - x_2)} \leftarrow k \right) \\
 &= \left(k[x_1, x_2] \xrightarrow{\begin{array}{l} x_1 \mapsto y \\ x_2 \mapsto y \end{array}} k[y] \leftarrow k \right) = \left[\text{Diagram: A circle with two nodes connected by a line, with a loop on the left node.} \right]
 \end{aligned} \tag{95}$$

Now for the soundness of $(\kappa\text{-TRP})$:

$$\begin{aligned}
 & \left[\text{Diagram: A circle with two nodes connected by a line, with a loop on the left node.} \right] \\
 &= \left(k[x_2] \rightarrow k \left[\begin{array}{l} x_1 \\ x_2 \end{array} \right] \xleftarrow{\begin{array}{l} x_1 \leftarrow y_1 \\ \kappa x_1 \leftarrow y_2 \\ x_2 \leftarrow y_3 \end{array}} k \left[\begin{array}{l} y_1 \\ y_2 \\ y_3 \end{array} \right] \xrightarrow{\begin{array}{l} y_1 \mapsto z_1 \\ y_2 \mapsto z_2 \\ y_3 \mapsto z_2 \end{array}} k[z_1] \leftarrow k[z_1] \right) \\
 &= \left(k[x_2] \rightarrow \frac{k[x_1, x_2, z_1, z_2]}{(x_1 - z_1, \kappa x_1 - z_2, x_2 - z_2)} \leftarrow k[z_1] \right) \\
 &= \left(k[x_2] \xrightarrow{x_2 \mapsto \kappa z_1} k[z_1] \leftarrow k[z_1] \right) = \left[\text{Diagram: A circle with two nodes connected by a line, with a loop on the left node.} \right]
 \end{aligned} \tag{96}$$

For the soundness of $(\kappa\text{-TRP})$:

$$\begin{aligned}
 & \left[\text{Diagram: A box containing a diagram with four nodes and a yellow semi-circle} \right] \\
 &= \left(k[x_3] \rightarrow k \left[\begin{smallmatrix} x_1 \\ x_2 \\ x_3 \end{smallmatrix} \right] \xleftarrow{\begin{smallmatrix} x_1 \leftarrow y_1 \\ x_1 x_2 \leftarrow y_2 \\ x_3 \leftarrow y_3 \\ x_2 \leftarrow y_4 \end{smallmatrix}} k \left[\begin{smallmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{smallmatrix} \right] \xrightarrow{\begin{smallmatrix} y_1 \mapsto z_1 \\ y_2 \mapsto z_2 \\ y_3 \mapsto z_2 \\ y_4 \mapsto z_3 \end{smallmatrix}} k \left[\begin{smallmatrix} z_1 \\ z_2 \\ z_3 \end{smallmatrix} \right] \leftarrow k \left[\begin{smallmatrix} z_1 \\ z_2 \\ z_3 \end{smallmatrix} \right] \right) \quad (97) \\
 &= \left(k[x_3] \rightarrow \frac{k[x_1, x_2, x_3, z_1, z_2, z_3]}{(x_1 - z_1, x_1 x_2 - z_2, x_3 - z_2, x_2 - z_3)} \leftarrow k \left[\begin{smallmatrix} z_1 \\ z_2 \\ z_3 \end{smallmatrix} \right] \right) \\
 &= \left(k[x_3] \xrightarrow{x_3 \mapsto z_1 z_3} k[z_1, z_3] \leftarrow k[z_1, z_3] \right) \\
 &= \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right]
 \end{aligned}$$

For the soundness of (ONE-TRP) :

$$\begin{aligned}
 & \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right] \\
 &= \left(k[x] \xleftarrow{\begin{smallmatrix} x \leftarrow y_1 \\ 1 \leftarrow y_2 \end{smallmatrix}} k[y_1, y_2] \xrightarrow{\begin{smallmatrix} y_1 \mapsto z \\ y_2 \mapsto z \end{smallmatrix}} k[z] \leftarrow k \right) \quad (98) \\
 &= \left(k[x] \rightarrow \frac{k[x, z]}{(x - z, 1 - z)} \leftarrow k \right) \\
 &= \left(k[x] \xrightarrow{x \mapsto 1} k \leftarrow k \right) = \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right]
 \end{aligned}$$

This completes the proof that every rewrite rule contained in figure 5 are sound with respect to the semantics functor $[-] : \mathbb{L}_{\text{Cosp}} \rightarrow_F \text{Cosp}(\text{CALg}_k^{\text{f.g.}})$. $\square$

B.2 Proofs of Derived Rules

Lemma 5.3. *The following are some useful derived rules of $\mathbb{L}_{\text{Cosp}}$:*

$$\begin{aligned}
 & \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right] = \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \quad (\text{special}) \\
 & \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right] = \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right] \quad \forall f \in (k[x_1, \dots, x_n])^m \quad (\text{poly-trp})
 \end{aligned}$$

PROOF. First we show how to derive special. The reasoning in this proof is almost identical to the reasoning in the proofs contained in appendix A.2.2 of [70]. We first make the following derivation: for any $\kappa \in k$,

$$\begin{aligned}
 & \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right] \stackrel{(\kappa\text{-TRP})}{=} \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right] \\
 & \stackrel{(\text{Z-FROB})}{=} \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right] \stackrel{(\text{Z-UNIT})}{=} \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right] \\
 & \stackrel{(\text{CUP})}{=} \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right] \stackrel{(\kappa\text{-ASSOC})}{=} \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right] \\
 & \stackrel{(\text{X-FROB})}{=} \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right] \quad (99)
 \end{aligned}$$

and with this we can make the desired derivation:

$$\begin{aligned}
 & \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \stackrel{(\text{X-BONE})}{=} \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \\
 & \stackrel{(\text{Z-UNIT})}{=} \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \\
 & \stackrel{(\text{ZERO-IN-K})}{=} \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \stackrel{(\text{K-ADD})}{=} \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \\
 & \stackrel{(\text{Z-ASSOC})}{=} \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \\
 & \stackrel{99}{=} \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \\
 & \stackrel{(\text{Z-ASSOC})}{=} \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \stackrel{(\text{X-ASSOC})}{=} \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \\
 & \stackrel{(\text{K-ADD})}{=} \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \stackrel{(\text{ZERO-IN-K})}{=} \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \\
 & \stackrel{(\text{Z-UNIT})}{=} \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \stackrel{(\text{X-UNIT})}{=} \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \quad (100)
 \end{aligned}$$

as required.

Next we show how to derive poly-trp by structural induction on $\mathbb{L}_{\text{CALg}_k}$. First we show that the proposition holds for $\overrightarrow{\Sigma f} = n$. When $n = 1$ this is easily derived as:

$$\text{LHS} = \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right] \stackrel{(\text{Z-FROB})}{=} \left[\text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} \right] \stackrel{(\text{Z-UNIT})}{=} \text{Diagram: A box containing a diagram with two nodes and a yellow semi-circle} = \text{RHS} \quad (101)$$

whereas for $n > 1$ we can induct on n :

$$\begin{aligned}
 LHS &= \text{Diagram with } n \text{ inputs and } n-1 \text{ outputs} \\
 &= \text{Diagram with } n-1 \text{ inputs and } n-1 \text{ outputs} \\
 &\stackrel{\text{I.H.}}{=} \text{Diagram with } n-1 \text{ inputs and } n-1 \text{ outputs} \\
 &= \text{Diagram with } n-1 \text{ inputs and } n-1 \text{ outputs} \\
 &\stackrel{3}{=} n \text{ } = RHS
 \end{aligned} \tag{102}$$

where the equality labelled “I.H.” is an application of the inductive hypothesis.

We then check that the proposition holds for f ranging over every generator of $\mathbb{L}_{\text{CAlg}_k}$.

If $\rightarrow f \leftarrow = \text{Diagram}$, then

$$\begin{aligned}
 LHS &= \text{Diagram} \stackrel{(Z-FROB)}{(Z-UNIT)}{=} \text{Diagram} \\
 &\stackrel{(Z-FROB)}{(Z-UNIT)}{=} \text{Diagram} \stackrel{(Z-FROB)}{(Z-UNIT)}{=} \text{Diagram} \\
 &\stackrel{(Z-SYMM)^\dagger}{=} \text{Diagram} = RHS
 \end{aligned} \tag{103}$$

If $\rightarrow f \leftarrow = \text{Diagram}$, the derivation is similar:

$$\begin{aligned}
 LHS &= \text{Diagram} \stackrel{(CUP)}{(CAP)}{(K-INV)}{=} \text{Diagram} \\
 &\stackrel{(X-FROB)}{(X-UNIT)}{=} \text{Diagram} \stackrel{(X-SYMM)}{=} \text{Diagram} \\
 &\stackrel{(K-ADD)}{=} \text{Diagram} \stackrel{(K-ASSOC)}{=} \text{Diagram} = RHS
 \end{aligned} \tag{104}$$

For $\rightarrow f \leftarrow = \text{Diagram}$ or Diagram , the proposition is a straightforward application of their respective (co)unitarity laws $(Z-UNIT)$ and $(X-UNIT)$. Finally, for $\rightarrow f \leftarrow = \text{Diagram}$, Diagram , or Diagram , the proposition is verbatim identical to the laws $(K-TRP)$, $(ONE-TRP)$, or $(K-TRP)$ respectively.

Now for the inductive step: suppose the proposition holds for $n \rightarrow f \leftarrow m$ and $n' \rightarrow g \leftarrow m'$. Then, in the case $m = n'$, consider the diagram $\rightarrow f \leftarrow \rightarrow g \leftarrow$. we have

$$\begin{aligned}
 LHS &= \text{Diagram} \\
 &\stackrel{102}{=} \text{Diagram} \stackrel{\text{I.H.}}{=} \text{Diagram} = RHS
 \end{aligned} \tag{105}$$

And for the diagram $\rightarrow f \leftarrow \rightarrow g \leftarrow$, we have

$$\begin{aligned}
 LHS &= \text{Diagram} = \text{Diagram} \\
 &\stackrel{\text{I.H.}}{=} \text{Diagram} = \text{Diagram} = RHS
 \end{aligned} \tag{106}$$

Where the second equality follows from the naturality of the braidings, and the fourth equality follows from both the naturality and the involutivity of the braidings. This completes the structural induction and proof. $\square$

B.3 Proofs about Ideal Gadgets

In this appendix we prove that the following lemmas hold in $\mathbb{L}_{\text{Cosp}}$.

Lemma 5.4. *For any $f \in k[x_1, \dots, x_n]$, the following is derivable from the rewrite rules of $\mathbb{L}_{\text{Cosp}}$:*

$$\text{Diagram} = \text{Diagram}$$

PROOF.

$$\begin{aligned}
 LHS &= \text{Diagram} \\
 &\stackrel{102}{=} \text{Diagram}
 \end{aligned}$$

$$\begin{aligned}
 & \text{poly-trp.poly-trp}^\dagger \\
 & \stackrel{(Z-FROB)}{=} \text{RHS}
 \end{aligned}$$

□

Lemma 5.5. For any $f, g \in k[x_1, \dots, x_n]$, the following is derivable from the rewrite rules of $\mathbb{L}_{\text{Cosp}}$:

$$\begin{aligned}
 & \text{LHS} = \text{Diagram 1} \stackrel{(Z-ASSOC)}{=} \text{Diagram 2} \\
 & \stackrel{(Z-SYMM)}{=} \text{Diagram 3} \stackrel{S.M.C.}{=} \text{Diagram 4} = \text{RHS}.
 \end{aligned} \tag{107}$$

Here the equality labelled S.M.C. follows from the naturality of the braidings in a symmetric monoidal category. □

Lemma 5.6. Let $f_1, \dots, f_m \in k[x_1, \dots, x_n]$, and pick some f inside the ideal $(f_1, \dots, f_m)$. Then the following is derivable from the rewrite rules of $\mathbb{L}_{\text{Cosp}}$:

$$\text{Diagram 1} = \text{Diagram 2}. \tag{26}$$

PROOF. First, by the completeness of $\mathbb{L}_{\text{CAlg}_k}$, we know that the following equation is derivable:

$$\text{Diagram 1} = \text{Diagram 2} = \text{Diagram 3}. \tag{108}$$

Note, the second equality here is verbatim rule (ZERO-IN-K) ; while the first equality can be easily derived by substituting

$$\text{Diagram 1} \stackrel{(\text{ONE-DEL})}{=} \text{Diagram 2} \stackrel{(\text{ZERO-IN-K})}{=} \text{Diagram 3}$$

Now, since $f \in (f_1, \dots, f_m)$, so there exist polynomials $g_1, \dots, g_m \in k[x_1, \dots, x_n]$ such that $f = g_1 f_1 + \dots + g_m f_m$. Then by the completeness of $\mathbb{L}_{\text{CAlg}_k}$, we know that the following is derivable by its rewrite rules:

$$\text{Diagram 1} = \text{Diagram 2} \tag{109}$$

Thus we can rewrite the right-hand-side of (26) as follows:

$$\begin{aligned}
 & \text{RHS} = \text{Diagram 1} \\
 & \stackrel{109}{=} \text{Diagram 2} \\
 & \stackrel{(Z-FROB)}{=} \text{Diagram 3} \\
 & \stackrel{(\text{POLY-COPY})}{=} \text{Diagram 4} \\
 & \stackrel{(\text{ZX-BIALG})}{=} \text{Diagram 5}
 \end{aligned}$$

(110)

Proposition 5.9 (Quotient Gadgets). *The semantic of the gadget*

is (any finite presentation of) the finitely generated commutative algebra defined by I . More precisely, if $I \subset k[x_1, \dots, x_n]$ is any ideal, then

$$\left[\begin{array}{c} \triangle I \\ \circ \\ \text{---} \end{array} \right] = (S_k(n) \twoheadrightarrow S_k(n)/I \leftarrow S_k(n))$$

where both legs are the canonical projections π_I against I .

PROOF. We first show this for the case where I is a principal ideal: say $I = (f)$. We view the gadget as a composition of two diagrams like so:

(111)

Note that the left-half is a diagram in $\mathbb{L}_{\text{CAlg}_k}$, while the right-half is a diagram in $\mathbb{L}_{\text{CAlg}_k}^{\text{op}}$. So

$$\begin{aligned} & \left[\begin{array}{c} \triangle f \\ \circ \\ \text{---} \end{array} \right] \\ &= \left(k[x_1, \dots, x_n] \xleftarrow[x_j \leftarrow y_j]{f(\mathbf{x}) \leftarrow y_0} k[y_0, \dots, y_n] \xrightarrow[y_j \mapsto z_j]{y_0 \mapsto 0} k[z_1, \dots, z_n] \right) \\ &= \left(k[x_1, \dots, x_n] \twoheadrightarrow \frac{k[x_1, \dots, x_n, z_1, \dots, z_n]}{(f(\mathbf{x}), x_j - z_j)} \leftarrow k[z_1, \dots, z_n] \right) \\ &= \left(k[x_1, \dots, x_n] \twoheadrightarrow \frac{k[x_1, \dots, x_n]}{(f(\mathbf{x}))} \leftarrow k[x_1, \dots, x_n] \right) \quad (112) \end{aligned}$$

where, in the derivation 112, the index j is always quantified universally over $1, \dots, n$.

Now we perform the inductive step: suppose that $I, J \subset k[x_1, \dots, x_n]$ are ideals for which the proposition holds. Then the composition

is the gadget corresponding to the ideal generated by the union of the elements in I and J (since we have taken a union of the generators). In other words it is the gadget corresponding to $I + J$. We compute:

$$\begin{aligned} & \left[\begin{array}{c} \triangle I \\ \triangle J \\ \circ \\ \text{---} \end{array} \right] \\ &= \left[\begin{array}{c} \triangle J \\ \circ \\ \text{---} \end{array} \right] \circ \left[\begin{array}{c} \triangle I \\ \circ \\ \text{---} \end{array} \right] \quad (113) \\ &= \left(k \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} \twoheadrightarrow k \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} / I \leftarrow k \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} \twoheadrightarrow k \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} / J \leftarrow k \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} \right) \\ &= \left(k \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} \twoheadrightarrow \frac{k[x_1, \dots, x_n]}{I + J} \leftarrow k \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} \right) \end{aligned}$$

Recall that, since $k[x_1, \dots, x_n]$ is a Noetherian ring, every ideal is a finite sum of principal ideals. This completes the induction and the proof. $\square$

B.4 Proofs about Universality and Completeness

Proposition 5.10 (Cospan Universality). *For any ideal $I \subset k[x_1, \dots, x_n]$ and tuples of polynomials $f \in (k[x_1, \dots, x_n])^m$ and $g \in (k[x_1, \dots, x_n])^{m'}$,*

$$\left[\begin{array}{c} \triangle I \\ \text{---} f \text{---} \triangle \text{---} g \text{---} \end{array} \right] = \left(S_k(m) \xrightarrow{f^\#} A \xleftarrow{g^\#} S_k(m') \right) \quad (29)$$

where $A = S_k(n)/I$. Since every algebra morphism $S_k(m) \rightarrow A$ is equal to $f^\#$ for some f , so $[-] : \mathbb{L}_{\text{Cosp}} \rightarrow_F \text{Cosp}(\text{CAlg}_k^{f, g})$ is full.

PROOF. Recall from proposition 5.9 that the semantic of the quotient gadget in the middle of the diagram on the left-hand-side is

$$\left[\begin{array}{c} \triangle I \\ \circ \\ \text{---} \end{array} \right] = (S_k(n) \twoheadrightarrow S_k(n)/I \leftarrow S_k(n)) \quad (114)$$

Thus we have

$$\begin{aligned} & \left[\text{Diagram: } \text{triangle } I \text{ on top of } f \text{ and } g \text{ in a box} \right] \\ &= \left(S_k(m) \xrightarrow{f^\#} S_k(n) \rightarrow S_k(n)/I \leftarrow S_k(n) \xleftarrow{g^\#} S_k(m') \right) \quad (115) \\ &= \left(S_k(m) \xrightarrow{f_I^\#} A \leftarrow g_I^\# S_k(m') \right) \end{aligned}$$

as required. $\square$

Proposition 5.12 (Cospin Normal Form). *Every diagram in $\mathbb{L}_{\text{Cosp}}$ can be rewritten into cospan form.*

PROOF. We prove by structural induction. First we show that every generator of $\mathbb{L}_{\text{Cosp}}$ can be rewritten into cospan form. By $\dagger$ -symmetry, we only need to show this for the generators coming from $\mathbb{L}_{\text{CALg}_k}$.

But this is immediate: for any $\text{Diagram} \in \mathbb{L}_{\text{CALg}_k}$, we may rewrite it as

$$\text{Diagram} \xrightarrow{(Z\text{-UNIT}), (X\text{-BONE})} \text{Diagram} \xrightarrow{5.7} \text{Diagram} \quad (116)$$

Thus all the generators of $\mathbb{L}_{\text{Cosp}}$ can be rewritten into cospan form. It remains now to show that compositions and monoidal products of cospan form diagrams can be rewritten into cospan form.

Take any pair of composable diagrams in cospan form. Their composition can be rewritten thus:

$$\begin{aligned} & \text{Diagram 1} \circ \text{Diagram 2} \\ & \xrightarrow{(Z\text{-FUSION})} \text{Diagram} \\ & \xrightarrow{(CAP), \text{poly-trp}} \text{Diagram} \\ & \xrightarrow{S.M.C.} \text{Diagram} \\ & \xrightarrow{5.7} \text{Diagram} \quad (117) \end{aligned}$$

Where the equality labelled “S.M.C.” is an application of the coherence axioms of symmetric monoidal categories. Note that this

corresponds precisely to the pushout operation taken in the composition of cospans.

Finally, take any pair of arbitrary diagrams in cospan form. Their monoidal product can be rewritten as:

$$\text{Diagram 1} \otimes \text{Diagram 2} \xrightarrow{S.M.C.} \text{Diagram}$$

which is again in cospan form. Thus by induction all diagrams in $\mathbb{L}_{\text{Cosp}}$ can be rewritten into cospan form. $\square$

Lemma 5.13. *Let $I \subset k[x_1, \dots, x_n]$ be an ideal, and let $f, g \in (k[x_1, \dots, x_n])^m$ be any two polynomial tuples such that $f - g \in I^m$. That is, let f, g be such that $f_I^\# = g_I^\#$. Then the following diagram rewrite is derivable in $\mathbb{L}_{\text{Cosp}}$:*

$$\text{Diagram 1} = \text{Diagram 2} \quad (31)$$

PROOF. Suppose $h = f - g \in I^m$. By Proposition 3.2

$$\text{Diagram} = \text{Diagram} \quad (118)$$

is a rewrite in $\mathbb{L}_{\text{CALg}_k}$. So we compute:

$$\begin{aligned} & \text{Diagram 1} = \text{Diagram 2} \\ & \xrightarrow{5.6} \text{Diagram} \xrightarrow{(Z\text{-ASSOC})} \text{Diagram} \\ & \xrightarrow{(POLY\text{-COPY})} \text{Diagram} \xrightarrow{(ZERO\text{-CP})} \text{Diagram} \\ & \xrightarrow{(X\text{-UNIT})} \text{Diagram} \xrightarrow{5.6} \text{Diagram} \quad (119) \end{aligned}$$

$\square$

Lemma 5.14. *Suppose $I \subset S_k(n)$ and $J \subset S_k(m)$ are ideals of polynomials and $f \in (S_k(n))^m$. Suppose $f_I^\# : S_k(m) \rightarrow S_k(n)/I$ satisfies $J \subset \ker f_I^\#$. Then the following rewrite holds:*

$$\text{Diagram 1} = \text{Diagram 2}$$

PROOF. Suppose $g_1, \dots, g_m$ is a basis $J = (g_1, \dots, g_m)$. Then for each g_j , we have $f_I^\#(g_j) = 0$. Using the definition of the $\#$, we have

in other words $(g_j \circ f)_I^\# = 0$. So $g_j \circ f \in I$. Thus by lemma 5.13, we have a rewrite

$$\begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{f} \xrightarrow{g_j} \text{---} \triangle I \text{---} \quad (120)$$

So we can derive:

$$\begin{array}{c} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{f} \begin{array}{c} \triangle J \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{5.7} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{f} \begin{array}{c} g_1 \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \dots \begin{array}{c} g_m \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{\text{(POLY-COPY)}} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{f} \begin{array}{c} g_1 \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \dots \begin{array}{c} g_m \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{f} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{\text{(Z-FROB)}, 5.8} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{f} \begin{array}{c} g_1 \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \dots \begin{array}{c} g_m \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{f} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{120} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{f} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \dots \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{f} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{\text{(Z-FROB)}, 5.8} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{f} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \dots \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{f} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{\text{(Z-UNIT)}, \text{(X-BONE)}} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{f} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \end{array}$$

Lemma 5.15. Suppose $I \subset S_k(n)$ and $J \subset S_k(m)$ are ideals, $\alpha : S_k(m)/J \rightarrow S_k(n)/I$ is an isomorphism of algebras, and $\sigma \in (k[x_1, \dots, x_n])^m$, $\tau \in (k[y_1, \dots, y_m])^n$ are a pair of polynomial tuples such that they represent α, α^{-1} respectively, i.e. such that the following commutes:

$$\begin{array}{ccccc} S_k(m) & \xrightarrow{\pi_J} & S_k(m)/J & \xleftarrow{\pi_J} & S_k(m) \\ \sigma^\# \downarrow & & \alpha^{-1} \uparrow \downarrow \alpha & & \uparrow \tau^\# \\ S_k(n) & \xrightarrow{\pi_I} & S_k(n)/I & \xleftarrow{\pi_I} & S_k(n) \end{array}$$

Then the following rewrite holds:

$$\begin{array}{c} \triangle J \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\tau} \text{---} \triangle I \text{---} \quad (32)$$

PROOF. We know that

$$\begin{aligned} \pi_I \circ \sigma^\# &= \alpha \circ \pi_J \\ \pi_J \circ \tau^\# &= \alpha^{-1} \circ \pi_I \end{aligned} \quad (122)$$

from which we can easily derive that

$$\begin{aligned} \pi_I \circ \sigma^\# \circ \tau^\# &= \pi_I \\ \pi_J \circ \tau^\# \circ \sigma^\# &= \pi_J \end{aligned} \quad (123)$$

which is to say,

$$\begin{aligned} (\tau \circ \sigma)_I^\# &= (id)_I^\# \\ (\sigma \circ \tau)_J^\# &= (id)_J^\# \end{aligned} \quad (124)$$

So by lemma 5.13, the following are derivable in $\mathbb{L}_{\text{Cosp}}$:

$$\begin{array}{c} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \xrightarrow{\tau} \text{---} \triangle I \text{---} \\ \begin{array}{c} \triangle J \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\tau} \xrightarrow{\sigma} \text{---} \triangle J \text{---} \end{array} \quad (125)$$

Now we can show that $\text{---} \triangle I \text{---} \xleftarrow{\sigma}$ is the left inverse of σ :

$$\begin{array}{c} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{\text{(Z-UNIT)}, \text{(POLY-DEL)}} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{\text{special}} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{\text{(POLY-COPY)}} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{\text{(Z-FROB)}, \text{poly-trp}} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{5.8, \text{(Z-FROB)}} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{125} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{\text{(Z-FROB)}, \text{(POLY-COPY)}} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{\text{(Z-FROB)}, \text{poly-trp}} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{\text{(POLY-COPY)}} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{\text{special}} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \\ \xrightarrow{\text{(POLY-DEL)}, \text{(Z-UNIT)}} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \xrightarrow{\sigma} \begin{array}{c} \triangle I \\ \downarrow \\ \text{---} \circ \text{---} \end{array} \end{array}$$

(126)

And consequently we have the rewrite we need:

□

Corollary 5.16. *If $\alpha : S_k(m)/J \rightarrow S_k(n)/I$ is an isomorphism of algebras, and $\sigma \in (k[x_1, \dots, x_n])^m$ represents α as in lemma 5.15, then*

PROOF.

□

Proposition 5.17. *The functor $[-]$ is faithful. That is, $\mathbb{L}_{\text{Cosp}}$ is complete as a language for $_{\text{F}} \text{Cosp}(\text{CALg}_k^{\text{f.g.}})$.*

PROOF. This is in other words to say that our rewrite rules are complete. By proposition 5.12 any diagram in $\mathbb{L}_{\text{Cosp}}$ can be rewritten into cospan form. So it suffices to prove that, whenever two diagrams in cospan form are mapped to isomorphic cospans by $[-]$, then they are rewriteable into each other. Pick any two diagrams in cospan form

with the same wire types on both ends. Suppose there exists a cospan isomorphism

(128)

between their images under the semantics functor.

Since $\alpha : S_k(v)/J \rightarrow S_k(u)/I$ is an isomorphism, so corollary 5.16 gives a rewrite

where σ is some tuple of polynomials such that $\sigma_I^\# = \alpha \circ \pi_J$ (say, pick $\sigma = (\alpha \circ \pi_J)_I^\#$). Moreover, since diagram 128 commutes, so

$$f_I^\# = \alpha \circ f_J^\# = \alpha \circ \pi_J \circ f'^\# = \sigma_I^\# \circ f'^\# = (f' \circ \sigma)_I^\# \quad (129)$$

and similarly we may derive $g_I^\# = (g' \circ \sigma)_I^\#$. So we have the following rewrites:

(130)

□

C Proofs about $\mathbb{L}_{\text{Span}_k}$ and $\mathbb{L}_{\text{Span}_q}$

C.1 Proofs about $\mathbb{L}_{\text{Span}_k}$

Proposition 6.2. *The PROP morphism*

$$\mathbb{L}_{\text{Cosp}} \xrightarrow{\text{Spec}[-]_{\text{red}}} \text{Span}(\text{AffVar}_k) \quad (34)$$

factors through $\mathbb{L}_{\text{Span}_k}$. In other words, rule (red) is sound for affine varieties over an algebraically closed field.

PROOF. We compute directly:

$$\begin{aligned} \text{Spec} \left[\text{---} \bigcirc \text{---} \bigcirc \text{---} \right]_{\text{red}} &= \text{Spec} \left(k[x] \xleftarrow{x^2} k[y] \xrightarrow{0} k \right)_{\text{red}} \\ &\stackrel{\text{pushout}}{=} \text{Spec} \left(k[x] \rightarrow k[x]/(x^2) \leftarrow k \right)_{\text{red}} \\ &\stackrel{\text{reduce}}{=} \text{Spec} \left(k[x] \xrightarrow{0} k = k \right) \\ &= \text{Spec} \left[\text{---} \bigcirc \text{---} \right]_{\text{red}} \end{aligned} \quad (131)$$

Thus rule red is sound with respect to the map $\text{Spec}[-]_{\text{red}}$, and so the map factors through $\mathbb{L}_{\text{Span}_k}$. □

Lemma 6.3. *Let $I \subset k[x_1, \dots, x_n]$ be an ideal. The following is derivable from the rewrite rules of $\mathbb{L}_{\text{Span}_k}$:*

$$\text{---} \bigcirc \text{---} = \text{---} \bigcirc \text{---} \quad (36)$$

PROOF. Since $\sqrt{I}$ will have a finite basis, so it suffices to prove that the following rewrite exists in $\mathbb{L}_{\text{Span}_k}$

$$\text{---} \bigcirc \text{---} = \text{---} \bigcirc \text{---} \quad (132)$$

for any $f \in \sqrt{I}$.

Since $f \in \sqrt{I}$, so there exists some $g \in I$ and some $n \in \mathbb{N}$ such that $g^n = f$. Thus by the completeness of $\mathbb{L}_{\text{CALg}_k}$ alone, the following is derivable:

$$\text{---} \bigcirc \text{---} = \text{---} \bigcirc \text{---} \quad (133)$$

So we have

$$\text{RHS} = \text{span of cospan diagrams} \stackrel{133}{=} \text{span of cospan diagrams} \stackrel{5,6}{=} \text{LHS}$$

□

Proposition 6.4. *The semantic map $\mathbb{L}_{\text{Span}_k} \xrightarrow{[-]_k} {}_G \text{Span}(\text{AffVar}_k)$ is faithful. In other words, $\mathbb{L}_{\text{Span}_k}$ is complete for ${}_G \text{Span}(\text{AffVar}_k)$.*

PROOF. Pick any ideals $I \subset S_k(u)$ and $J \subset S_k(v)$, and any tuples of polynomials $f \in (k[x_1, \dots, x_n])^u$, $f' \in (k[x_1, \dots, x_n])^v$, $g \in (k[y_1, \dots, y_m])^u$, and $g' \in (k[y_1, \dots, y_m])^v$. Suppose that the following diagrams are sent to the same semantic by $[-]_k$:

$$\left[\text{cospan}(I, f, g) \right]_k = \left[\text{cospan}(J, f', g') \right]_k \quad (134)$$

that is, there is a span isomorphism of varieties

$$\begin{aligned} \text{Spec} \left(S_k(n) \xrightarrow{f_I^\#} S_k(u)/I \xleftarrow{g_I^\#} S_k(m) \right)_{\text{red}} \\ = \text{Spec} \left(S_k(n) \xrightarrow{f_J^\#} S_k(v)/J \xleftarrow{g_J^\#} S_k(m) \right)_{\text{red}} \end{aligned} \quad (135)$$

Since $\text{Spec} : \text{CAlg}_k^{\text{f.g., red.}} \rightarrow \text{AffVar}_k^{\text{op}}$ is an equivalence of categories (Proposition 2.20), so this means

$$\begin{aligned} \left(S_k(n) \xrightarrow{f_I^\#} S_k(u)/I \xleftarrow{g_I^\#} S_k(m) \right)_{\text{red}} \\ = \left(S_k(n) \xrightarrow{f_J^\#} S_k(v)/J \xleftarrow{g_J^\#} S_k(m) \right)_{\text{red}} \end{aligned} \quad (136)$$

which is to say, there is an isomorphism of cospans of algebras

$$\begin{aligned} \left(S_k(n) \xrightarrow{f_{\sqrt{I}}^\#} S_k(u)/\sqrt{I} \xleftarrow{g_{\sqrt{I}}^\#} S_k(m) \right) \\ = \left(S_k(n) \xrightarrow{f_{\sqrt{J}}^\#} S_k(v)/\sqrt{J} \xleftarrow{g_{\sqrt{J}}^\#} S_k(m) \right) \end{aligned} \quad (137)$$

Thus, by the completeness of $\mathbb{L}_{\text{Cosp}}$ for ${}_F \text{Cosp}(\text{CAlg}_k^{\text{f.g.}})$ (Proposition 5.17), the following rewrite exists under just the rules of $\mathbb{L}_{\text{Cosp}}$:

$$\text{cospan}(\sqrt{I}, f, g) = \text{cospan}(\sqrt{J}, f', g') \quad (138)$$

Thus with lemma 6.3 we obtain the series of rewrites

$$\begin{aligned} \text{cospan}(I, f, g) &= \text{cospan}(\sqrt{I}, f, g) \\ &= \text{cospan}(\sqrt{J}, f, g) \\ &= \text{cospan}(J, f, g) \end{aligned} \quad (139)$$

□

Proposition 6.7. *The PROP morphism*

$$\mathbb{L}_{\text{Cosp}} \xrightarrow{\text{Spec}[-]_{qred}} {}_{G_q} \text{Span}(\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)}) \quad (37)$$

factors through $\mathbb{L}_{\text{Span}_q}$. In other words, the rule $qred$ is sound with respect to $\mathbb{F}_q$ -rational loci.

PROOF. We compute directly:

$$\begin{aligned} \text{Spec} \left[\text{cospan}(q) \right]_{qred} \\ = \text{Spec} \left(k[x] = k[x] \xleftarrow{x^q} k[y] \right)_{qred} \\ = \text{Spec} \left(k[x]/(x^q - x) = k[x]/(x_q - x) \xleftarrow{x} k[y]/(y^q - y) \right) \\ = \text{Spec} \left(k[x]/(x^q - x) = k[x]/(x_q - x) = k[x]/(x^q - x) \right) \\ = \text{Spec} \left(k[x] = k[x] = k[x] \right)_{qred} \\ = \text{Spec} [\text{cospan}(q)]_{qred} \end{aligned} \quad (140)$$

□

Lemma 6.8. *For $\Gamma_q^n = \{x_1^q, \dots, x_n^q\}$, the following is derivable from*

the rewrite rules of $\mathbb{L}_{\text{Span}_q}$: $\text{cospan}(\Gamma_q^n) = \text{cospan}(-1)$

PROOF. Recall from 2.25 that $\Gamma_q^n \subset k[x_1, \dots, x_n]$ is the ideal generated by $x_1^q - x_1, \dots, x_n^q - x_n$. Thus

$$\begin{aligned} \text{cospan}(\Gamma_q^n, q, -1) &= \text{cospan}(-1, -1) \\ &\stackrel{qred}{=} \text{cospan}(-1, -1) \\ &\stackrel{(K-ADD)}{=} \text{cospan}(0, -1) \\ &\stackrel{(ZERO-IN-K)}{=} \text{cospan}(0, -1) \\ &\stackrel{(Z-UNIT), (X-BONE)}{=} \text{cospan}(0, -1) \end{aligned} \quad (141)$$

9

Proposition 6.9. *The semantic map $[-]_q$ is faithful. In other words, the rules of $\mathbb{L}_{\text{Span}_q}$ are complete.*

PROOF. For ideals $I \subset S_k(u)$ and $J \subset S_k(v)$, and tuples of polynomials $f \in (k[x_1, \dots, x_n])^u$, $f' \in (k[x_1, \dots, x_n])^v$, $g \in (k[y_1, \dots, y_m])^u$, and $g' \in (k[y_1, \dots, y_m])^n$. Suppose that the following diagrams are sent to the same semantic by $[-]_q$:

$$\left[\text{Diagram with } f, I, g \right]_q = \left[\text{Diagram with } f', J, g' \right]_q \quad (142)$$

that is, there is a span isomorphism of varieties

$$\begin{aligned} & \text{Spec} \left(S_{\mathbb{F}_q}(n) \xrightarrow{f_I^\#} S_{\mathbb{F}_q}(u)/I \xleftarrow{g_I^\#} S_{\mathbb{F}_q}(m) \right)_{qred} \\ &= \text{Spec} \left(S_{\mathbb{F}_q}(n) \xrightarrow{f_J^\#} S_{\mathbb{F}_q}(v)/J \xleftarrow{g_J^\#} S_{\mathbb{F}_q}(m) \right)_{qred} \end{aligned} \quad (143)$$

Since $\text{Spec} : \text{CAlg}_{\mathbb{F}_q}^{\text{f.g., qred.}} \rightarrow \text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)^{op}}$ is an equivalence of categories (Proposition 2.27), so this means

$$\begin{aligned}
& \left(S_{\mathbb{F}_q}(n) \xrightarrow{f_J^\#} S_{\mathbb{F}_q}(u)/I \xleftarrow{g_I^\#} S_{\mathbb{F}_q}(m) \right)_{qred} \\
& = \left(S_{\mathbb{F}_q}(n) \xrightarrow{f_J^\#} S_{\mathbb{F}_q}(v)/J \xleftarrow{g_J^\#} S_{\mathbb{F}_q}(m) \right)_{qred}
\end{aligned} \tag{144}$$

which is to say, there is an isomorphism of cospans of algebras

$$\begin{aligned}
& \left(\frac{S_{\overline{F}q}(n)}{\Gamma_q^n} \xrightarrow{(f_J^*)_{qred}} \frac{S_{\overline{F}q}(u)}{I + \Gamma_q^u} \xleftarrow{(g_J^*)_{qred}} \frac{S_{\overline{F}q}(m)}{\Gamma_q^m} \right) \\
&= \left(\frac{S_{\overline{F}q}(n)}{\Gamma_q^n} \xrightarrow{(f_J^{**})_{qred}} \frac{S_{\overline{F}q}(v)}{J + \Gamma_q^v} \xleftarrow{(g_J^{**})_{qred}} \frac{S_{\overline{F}q}(m)}{\Gamma_q^m} \right) \quad (145)
\end{aligned}$$

Composing both sides of the equation with projections maps we obtain isomorphisms of cospans

$$\begin{aligned}
& \left(S_{\mathbb{F}_q}(n) \twoheadrightarrow \frac{S_{\mathbb{F}_q}(n)}{\Gamma_q^n} \xrightarrow{(f_I^\#)_{qred}} \frac{S_{\mathbb{F}_q}(u)}{I + \Gamma_q^u} \xleftarrow{(g_I^\#)_{qred}} \frac{S_{\mathbb{F}_q}(m)}{\Gamma_q^m} \leftarrow S_{\mathbb{F}_q}(m) \right) \\
&= \left(S_{\mathbb{F}_q}(n) \twoheadrightarrow \frac{S_{\mathbb{F}_q}(n)}{\Gamma_q^n} \xrightarrow{(f_J^\#)_{qred}} \frac{S_{\mathbb{F}_q}(v)}{J + \Gamma_q^v} \xleftarrow{(g_J^\#)_{qred}} \frac{S_{\mathbb{F}_q}(m)}{\Gamma_q^m} \leftarrow S_{\mathbb{F}_q}(m) \right)
\end{aligned} \tag{146}$$

Now recall, that for an algebra morphism $\varphi : A \rightarrow B$, the morphism $\varphi_{qred} : A/\Gamma_q(A) \rightarrow B/\Gamma_q(B)$ is the unique morphism making the following commute:

$$\begin{array}{ccc} A & \xrightarrow{\varphi} & B \\ \Downarrow & & \Downarrow \\ A/\Gamma_q(A) & \xrightarrow{\varphi_{\text{red}}} & B/\Gamma_q(B) \end{array}$$

so in particular, equation 146 becomes

$$\begin{aligned}
& \left(S_{\mathbb{F}_q}(n) \xrightarrow{f_{I+\Gamma_q^u}^\#} \frac{S_{\mathbb{F}_q}(u)}{I + \Gamma_q^u} \xleftarrow{g_{I+\Gamma_q^u}^\#} S_{\mathbb{F}_q}(m) \right) \\
&= \left(S_{\mathbb{F}_q}(n) \xrightarrow{f_{J+\Gamma_q^v}^\#} \frac{S_{\mathbb{F}_q}(v)}{J + \Gamma_q^v} \xleftarrow{g_{J+\Gamma_q^v}^\#} S_{\mathbb{F}_q}(m) \right)
\end{aligned} \tag{147}$$

Thus by the completeness of $\mathbb{L}_{\text{Cosp}}$ for ${}_F \text{Cosp}(\text{CAI}_g^{\text{f.g.}})$, the following rewrite can be derived from just the rewrite rules of $\mathbb{L}_{\text{Cosp}}$:

$$\begin{array}{c} \triangle I \\ | \\ \text{---} f \text{---} \bigcirc \text{---} \bigcirc \text{---} g \text{---} \end{array} = \begin{array}{c} \triangle J \\ | \\ \text{---} f' \text{---} \bigcirc \text{---} \bigcirc \text{---} g' \text{---} \end{array} \quad (148)$$

Thus, with lemma 6.8, we obtain the following series of rewrites:

$$\begin{aligned}
& \text{Diagram 1} = \text{Diagram 2} \\
& \text{Diagram 2} = \text{Diagram 3} \\
& \text{Diagram 3} = \text{Diagram 4}
\end{aligned}
\tag{149}$$

Thus any two diagrams with the same semantic under $[-]_q$ are rewriteable into each other with the rules of $\mathbb{L}_{\text{Span}_q}$. So $[-]_q$ is faithful. $\square$

C.2 Proofs about $\text{Mat}_{\mathbb{N}}$ semantics for $\mathbb{L}_{\text{Span}_q}$

Proposition 6.12. *The functor M_q is well-defined and fully faithful.*

PROOF. First consider the identity $\text{span } \mathbb{F}_q^n \xleftarrow{id} \mathbb{F}_q^n \xrightarrow{id} \mathbb{F}_q^n$. For each pair $\mathbf{x}, \mathbf{y} \in \mathbb{F}_q^n$, it is clear that

$$M_q \left(\begin{array}{c} id \quad id \\ \longleftrightarrow \end{array} \right)_{xy} = \delta_{x,y} \quad (150)$$

and so $M_q \left(\begin{smallmatrix} id & id \\ \longleftarrow & \longrightarrow \end{smallmatrix} \right)$ is the identity matrix.

Next suppose we have a composition of two structured spans of rational loci over $\mathbb{F}_q$:

$$\begin{array}{ccccc}
 & & V \times_{\psi, \phi'} W & & \\
 & \swarrow \pi_V & & \searrow \pi_W & \\
 V & & & & W \\
 \swarrow \phi & & \searrow \psi & \swarrow \phi' & \searrow \psi' \\
 \mathbb{F}_q^n & & \mathbb{F}_q^m & & \mathbb{F}_q^n
 \end{array}$$

The set of points in the pullback $V \times_{\psi, \psi'} W$ is the set of pairs $(\mathbf{v}, \mathbf{w}) \in V \times W$ such that $\psi \mathbf{v} = \psi' \mathbf{w}$. So we compute, for $\mathbf{x} \in \mathbb{F}_q^n, \mathbf{z} \in \mathbb{F}_q^{n'}$:

$$\begin{aligned} M \left(\begin{array}{c} \phi \quad \psi \quad \phi' \quad \psi' \\ \leftarrow \quad \rightarrow \quad \leftarrow \quad \rightarrow \\ \text{xx} \end{array} \right) &= |\{(\mathbf{v}, \mathbf{w}) \in V \times W : \psi \mathbf{v} = \phi' \mathbf{w}, \phi \mathbf{v} = \mathbf{x}, \psi' \mathbf{w} = \mathbf{z}\}| \\ &= \left| \bigcup_{\mathbf{y} \in \mathbb{F}_q^m} \left\{ (\mathbf{v}, \mathbf{w}) \in V \times W : \begin{array}{l} \phi \mathbf{v} = \mathbf{x} \quad \phi' \mathbf{w} = \mathbf{y} \\ \psi \mathbf{v} = \mathbf{y} \quad \psi' \mathbf{w} = \mathbf{z} \end{array} \right\} \right| \\ &= \sum_{\mathbf{y} \in \mathbb{F}_q^m} \left| \left\{ \mathbf{v} \in V : \begin{array}{l} \phi \mathbf{v} = \mathbf{x} \\ \psi \mathbf{v} = \mathbf{y} \end{array} \right\} \times \left\{ \mathbf{w} \in W : \begin{array}{l} \phi' \mathbf{w} = \mathbf{y} \\ \psi' \mathbf{w} = \mathbf{z} \end{array} \right\} \right| \\ &= \sum_{\mathbf{y} \in \mathbb{F}_q^m} M_q \left(\begin{array}{c} \phi \quad \psi \\ \leftarrow \quad \rightarrow \\ \text{xy} \end{array} \right) M_q \left(\begin{array}{c} \phi' \quad \psi' \\ \leftarrow \quad \rightarrow \\ \text{yz} \end{array} \right) \end{aligned} \quad (151)$$

and therefore,

$$M \left(\begin{array}{c} \phi \quad \psi \quad \phi' \quad \psi' \\ \leftarrow \quad \rightarrow \quad \leftarrow \quad \rightarrow \end{array} \right) = M_q \left(\begin{array}{c} \phi \quad \psi \\ \leftarrow \quad \rightarrow \end{array} \right) M_q \left(\begin{array}{c} \phi' \quad \psi' \\ \leftarrow \quad \rightarrow \end{array} \right) \quad (152)$$

As required.

We now prove fullness and faithfulness separately. $\square$

Lemma C.1. *The functor M_q is full.*

PROOF. It's clear that the objects in the image of M_q are q^n , with $n \in \mathbb{N}$. Let A be an $\mathbb{N}$ -matrix of dimensions $q^n \times q^m$, which we interpret as a function $A : \mathbb{F}_q^n \times \mathbb{F}_q^m \rightarrow \mathbb{N}$. Pick a number $N \in \mathbb{N}$ such that

$$q^N > \max_{\substack{\mathbf{x} \in \mathbb{F}_q^n \\ \mathbf{y} \in \mathbb{F}_q^m}} A_{\mathbf{x}\mathbf{y}} \quad (153)$$

Then for $\mathbf{x} \in \mathbb{F}_q^n, \mathbf{y} \in \mathbb{F}_q^m$, we can find some subset $V_{\mathbf{x}\mathbf{y}} \subset \mathbb{F}_q^N$ such that $|V_{\mathbf{x}\mathbf{y}}| = A_{\mathbf{x}\mathbf{y}}$. Then consider the set $V \subset \mathbb{F}_q^n \times \mathbb{F}_q^m \times \mathbb{F}_q^N$ defined by

$$V = \bigcup_{\substack{\mathbf{x} \in \mathbb{F}_q^n \\ \mathbf{y} \in \mathbb{F}_q^m}} \{\mathbf{x}\} \times \{\mathbf{y}\} \times V_{\mathbf{x}\mathbf{y}} \quad (154)$$

Since every subset of affine spaces over $\mathbb{F}_q$ is an affine variety (this is a well-known elementary fact, see for example [31, 54]), so V is an affine variety. Then consider the structured span

$$\mathbb{F}_q^n \xleftarrow{\pi_x} V \xrightarrow{\pi_y} \mathbb{F}_q^m \quad (155)$$

where π_x, π_y are the restrictions of the projection maps

$$\mathbb{F}_q^n \leftarrow \mathbb{F}_q^n \times \mathbb{F}_q^m \times \mathbb{F}_q^N \rightarrow \mathbb{F}_q^m. \quad (156)$$

This is a morphism in $G_q \text{Span}(\text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)})$, and

$$M_q \left(\begin{array}{c} \pi_x \quad \pi_y \\ \leftarrow \quad \rightarrow \end{array} \right)_{\mathbf{xy}} = |V_{\mathbf{x}\mathbf{y}}| = A_{\mathbf{x}\mathbf{y}} \quad (157)$$

Thus A is in the image of M_q . $\square$

Lemma C.2. *The functor M_q is faithful.*

PROOF. Suppose two structured spans of rational loci over $\mathbb{F}_q$ which are mapped by M_q to the same $\mathbb{N}$ -matrix:

$$M_q \left(\begin{array}{c} \phi \quad \psi \\ \leftarrow \quad \rightarrow \\ \mathbb{F}_q^n \quad \mathbb{F}_q^m \end{array} \right) = M_q \left(\begin{array}{c} \phi' \quad \psi' \\ \leftarrow \quad \rightarrow \\ \mathbb{F}_q^n \quad \mathbb{F}_q^m \end{array} \right) \quad (158)$$

Then for each pair $\mathbf{x} \in \mathbb{F}_q^n, \mathbf{y} \in \mathbb{F}_q^m$, there exists some set-theoretic bijection

$$\sigma_{\mathbf{x}\mathbf{y}} : \phi^{-1}(\mathbf{x}) \cap \psi^{-1}(\mathbf{y}) \rightarrow \phi'^{-1}(\mathbf{x}) \cap \psi'^{-1}(\mathbf{y}) \quad (159)$$

These bijections can be glued into

$$\begin{aligned} \sigma : V &\rightarrow W \\ \mathbf{v} &\mapsto \sigma_{\phi \mathbf{v}, \psi \mathbf{v}}(\mathbf{v}) \end{aligned} \quad (160)$$

Since every function between rational loci over $\mathbb{F}_q$ is a polynomial mapping [31], so σ is a polynomial mapping. Moreover, by construction the following commutes:

$$\begin{array}{ccc} & V & \\ \phi \swarrow & & \searrow \psi \\ \mathbb{F}_q^n & & \mathbb{F}_q^m \\ \phi' \swarrow & \sigma & \searrow \psi' \\ & W & \end{array}$$

and therefore σ is a structured span isomorphism. $\square$

D Proof of GAG as CSP

Proposition 7.1. *Let $\langle X, C \rangle$ be a CSP instance over the domain $\mathbb{F}_q$, with set of variables $X = \{x_1, \dots, x_n\}$, and polynomial constraints $g_1, \dots, g_m \in k[x_1, \dots, x_n]$. Let I be the ideal generated by $g_1, \dots, g_m$. Then the span semantic of the ideal gadget is*

$$n \begin{array}{c} \triangle \\ | \\ \bigcirc \end{array} n \xrightarrow{[-]_q} \left(\mathbb{F}_q^n \leftarrow V(I)^{\mathbb{F}_q} \hookrightarrow \mathbb{F}_q^n \right) \quad (42)$$

where, recall, $V(I)^{\mathbb{F}_q} := \{\mathbf{x} \in \mathbb{F}_q^n : g_1(\mathbf{x}) = \dots = g_m(\mathbf{x}) = 0\}$. In other words, it is the set of assignments satisfying $\langle X, C \rangle$.

The same diagram with no wires on either side has the following matrix semantic:

$$\begin{array}{c} \triangle \\ | \\ \bigcirc \end{array} \xrightarrow{[-]_q} |V(I)^{\mathbb{F}_q}| \quad (43)$$

In other words, it is the number of assignments that satisfy $\langle X, C \rangle$.

PROOF. We know from proposition 5.9 that the *cospan semantic* of the ideal gadget is

$$\left[n \begin{array}{c} \triangle \\ | \\ \bigcirc \end{array} n \right] = (S_k(n) \rightarrow S_k(n)/I \leftarrow S_k(n)) \quad (161)$$

Hitting the cospan of algebras with the functor $\text{Spec}(-)_{\text{qred}} : \text{CAlg}_{\mathbb{F}_q}^{\text{f.g.}} \rightarrow \text{AffVar}_{\mathbb{F}_q}^{(\mathbb{F}_q)}$ yields equation 42. Then equation 43 follows immediately by composing on both left and right legs with the projection $\mathbb{F}_q^n \xrightarrow{!} *$ where $*$ is the singleton. $\square$

E Proofs about ZH calculus as an extension of GAG

Proposition 8.6. *The functor ι_{ZH} is consistent with the semantics of the ZH Calculus. In other words, the following diagram commutes:*

$$\begin{array}{ccc} \mathbb{L}_{\text{Span}_q}^{\text{Fourier}} & \xrightarrow{[-]_q^{\text{Fourier}}} & q^{\frac{*}{2}} \text{Mat}_{\mathbb{Z}[\omega]} \\ \uparrow \iota_{\text{ZH}} & \nearrow [-]_{\text{ZH}} & \\ \text{ZH} & & \end{array}$$

PROOF. We check that the image of each generator of ZH under ι_{ZH} is mapped to the same matrix as under $\llbracket - \rrbracket_{\text{ZH}}$.
Z-spider:

$$\left[\begin{array}{c} n \\ \vdots \\ \text{Z-spider} \\ \vdots \\ m \end{array} \right]_q^{\text{Fourier}} = \sum_{i \in \mathbb{F}_q} |i\rangle^{\otimes m} \langle i|^{\otimes n} = \left[\begin{array}{c} n \\ \vdots \\ \text{Z-spider} \\ \vdots \\ m \end{array} \right]_{\text{ZH}}$$

H-spider:

$$\left[\begin{array}{c} q^{-\frac{1}{2}} \\ \text{H-spider} \\ \vdots \\ n \\ \vdots \\ m \end{array} \right]_q^{\text{Fourier}} \quad (162)$$

$$= \frac{1}{\sqrt{q}} \left(\sum_{\substack{j_1, \dots, j_m \in \mathbb{F}_q \\ i_1, \dots, i_n \in \mathbb{F}_q}} |j_1\rangle \dots |j_m\rangle \langle i_1| \dots \langle i_n| \otimes \langle j_1 \dots j_m i_1 \dots i_n| \right) \left(\sum_{k \in \mathbb{F}_q} \omega^{\text{tr}(k)} |k\rangle \right) \quad (163)$$

$$= \frac{1}{\sqrt{q}} \sum_{\substack{j_1, \dots, j_m \in \mathbb{F}_q \\ i_1, \dots, i_n \in \mathbb{F}_q}} \omega^{\text{tr}(j_1 \dots j_m i_1 \dots i_n)} |j_1\rangle \dots |j_m\rangle \langle i_1| \dots \langle i_n| \quad (164)$$

$$= \left[\begin{array}{c} n \\ \vdots \\ \text{H-spider} \\ \vdots \\ m \end{array} \right]_{\text{ZH}} \quad (165)$$

X-basis state:

$$\left[\begin{array}{c} \text{X-basis state} \\ \vdots \\ j \\ \vdots \\ q^{-\frac{1}{2}} \end{array} \right]_q^{\text{Fourier}} = q^{-\frac{1}{2}} q \left(\sum_{i \in \mathbb{F}_q} |ji\rangle \langle i| \right) |1\rangle = \sqrt{q} |j\rangle = \left[\begin{array}{c} j \\ \text{X-basis state} \end{array} \right]_{\text{ZH}} \quad (166)$$

□

Proposition 8.4. The rewrite rules in equation (47) are sound with respect to the semantics $\llbracket - \rrbracket_q^{\text{Fourier}}$.

PROOF. First we check the (Z1-COPY) rule:

$$\llbracket [L.H.S.]_q^{\text{Fourier}} \rrbracket = \left(\sum_{j,k \in \mathbb{F}_q} |j\rangle \langle k| \langle j+k| \right) \left(\sum_{i \in \mathbb{F}_q} \omega^{\text{tr}(i)} |i\rangle \right) \quad (167)$$

$$= \sum_{j,k \in \mathbb{F}_q} \omega^{\text{tr}(j+k)} |j\rangle \langle k| \quad (168)$$

$$= \left(\sum_{j \in \mathbb{F}_q} \omega^{\text{tr}(j)} |j\rangle \right) \otimes \left(\sum_{k \in \mathbb{F}_q} \omega^{\text{tr}(k)} |k\rangle \right) \quad (169)$$

$$= \llbracket [R.H.S.]_q^{\text{Fourier}} \rrbracket \quad (170)$$

Next we check the (Z1-DEL) rule:

$$\llbracket [L.H.S.]_q^{\text{Fourier}} \rrbracket = \langle 0 | \left(\sum_{i \in \mathbb{F}_q} \omega^{\text{tr}(i)} |i\rangle \right) = \omega^{\text{tr}(0)} = 1 = \llbracket [R.H.S.]_q^{\text{Fourier}} \rrbracket \quad (171)$$

□

Proposition 8.7. For any diagram D in $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$, there exists $k \in \mathbb{N}$ and a diagram D' containing only the generators of $\mathbb{L}_{\text{Span}_q}$ such that

$$\left[\begin{array}{c} \vdots \\ D \\ \vdots \end{array} \right] = \left[\begin{array}{c} \vdots \\ D' \\ \text{1} \end{array} \right] \left[\begin{array}{c} q^{-\frac{1}{2}} \end{array} \right]^{(\otimes k)} \quad (50)$$

PROOF. For all $\left[\begin{array}{c} q^{-\frac{1}{2}} \end{array} \right]$ in D , we can pull them out to the front of the diagram using the monoidal structure. Then we only need to consider the instances of the 1 generator. This holds trivially if the diagram D contains a single instance of the 1 generator. If there are two or more instances, we can use the (Z1-COPY) rule to merge multiple instances into one. When there are no instances of 1 , we can use the (Z1-DEL) rule in reverse to introduce one copy. □

Theorem 8.8. Let D be a scalar diagram in the ZH calculus over $\mathbb{F}_q$. The scalar $\llbracket D \rrbracket_{\text{ZH}}$ can be computed using exactly q queries to an oracle $\mathcal{O}$ that evaluates the semantics of scalar diagrams in $\mathbb{L}_{\text{Span}_q}$.

PROOF. From Proposition 8.6, we have that $\llbracket D \rrbracket_{\text{ZH}} = \llbracket \iota_{\text{ZH}}(D) \rrbracket_q^{\text{Fourier}}$.

$$\begin{aligned} \llbracket \iota_{\text{ZH}}(D) \rrbracket_q^{\text{Fourier}} &= \left[\begin{array}{c} D' \\ \text{1} \end{array} \right]_q^{\text{Fourier}} \left[\begin{array}{c} q^{-\frac{1}{2}} \end{array} \right]^{(\otimes k)} = q^{-\frac{k}{2}} \sum_{j \in \mathbb{F}_q} \left[\begin{array}{c} D' \\ j \end{array} \right]_q^{\text{Fourier}} \\ &= q^{-\frac{k}{2}} \sum_{j \in \mathbb{F}_q} \left[\begin{array}{c} D' \\ j \end{array} \right]_{\text{ZH}} \end{aligned}$$

Thus, we can compute $\llbracket D \rrbracket_{\text{ZH}}$ using q queries to the oracle $\mathcal{O}$ that computes $\llbracket - \rrbracket_q$ on scalar diagrams in $\mathbb{L}_{\text{Span}_q}$. □

F Proofs about ZH completeness

Proposition 9.2. If

$$\left[\begin{array}{c} D_1 \\ \text{1} \end{array} \right] \stackrel{n}{=} \left[\begin{array}{c} D_2 \\ \text{1} \end{array} \right]$$

are diagrams in $\mathbb{L}_{\text{Span}_q}$, such that

$$\left[\begin{array}{c} D_1 \\ \text{1} \end{array} \right]_{\text{ZH}} = \left[\begin{array}{c} D_2 \\ \text{1} \end{array} \right]_{\text{ZH}} \quad (52)$$

and satisfying the following restriction condition: for all $x \in \mathbb{F}_q$ except for those lying on one line $\xi \mathbb{F}_p$ where ξ is some fixed element of field trace 1,

$$\left[\begin{array}{c} D_1 \\ x \end{array} \right]_{\text{ZH}} = \left[\begin{array}{c} D_2 \\ x \end{array} \right]_{\text{ZH}} = 0 \quad (53)$$

Then there exist diagrams $\left[\begin{array}{c} C_1 \\ \text{1} \end{array} \right] \stackrel{n}{=}$ and $\left[\begin{array}{c} C_2 \\ \text{1} \end{array} \right] \stackrel{n}{=}$ in $\mathbb{L}_{\text{Span}_q}$ such that

$$\left[\begin{array}{c} D_1 \\ \text{1} \end{array} \right]_q + \left[\begin{array}{c} C_1 \\ \text{1} \end{array} \right]_q = \left[\begin{array}{c} D_2 \\ \text{1} \end{array} \right]_q + \left[\begin{array}{c} C_2 \\ \text{1} \end{array} \right]_q \quad (54)$$

PROOF.

$$\left[\begin{array}{c} D_1 \\ \text{1} \end{array} \right]_{\text{ZH}} = \left[\begin{array}{c} D_2 \\ \text{1} \end{array} \right]_{\text{ZH}} \quad (172)$$

$$\Rightarrow \sum_{x \in \mathbb{F}_q} \omega^{\text{tr}(x)} \left[\begin{array}{c} D_1 \\ x \end{array} \right]_{\text{ZH}} = \sum_{x \in \mathbb{F}_q} \omega^{\text{tr}(x)} \left[\begin{array}{c} D_2 \\ x \end{array} \right]_{\text{ZH}} \quad (173)$$

$$\Rightarrow \sum_{x \in \mathbb{F}_q} \omega^{\text{tr}(x)} \left[\left[D_1 \right] \overline{\left[x \right]} \right]_q = \sum_{x \in \mathbb{F}_q} \omega^{\text{tr}(x)} \left[\left[D_2 \right] \overline{\left[x \right]} \right]_q \quad (174)$$

$$\Rightarrow \sum_{x \in \xi \mathbb{F}_p} \omega^{\text{tr}(x)} \left[\left[\boxed{D_1} \overline{\circledast x} \right] \right]_q = \sum_{x \in \xi \mathbb{F}_p} \omega^{\text{tr}(x)} \left[\left[\boxed{D_2} \overline{\circledast x} \right] \right]_q \quad (175)$$

$$\Rightarrow \sum_{x \in \xi_{\mathbb{F}_p}^{\mathbb{F}_p}} \omega^x \left[\left[D_1 \right] \overline{x} \right]_q = \sum_{x \in \xi_{\mathbb{F}_p}^{\mathbb{F}_p}} \omega^x \left[\left[D_2 \right] \overline{x} \right]_q \quad (176)$$

Using the fact that $\omega^0 = -\sum_{x \in \xi_{\rho}^{\text{TF}^{\times}}} \omega^x$, we can rewrite the above as

$$\begin{aligned} & \sum_{x \in \xi_{\mathbb{P}^{\times}}^{\times}} \omega^x \left(\left[\left[D_1 \right] \right]_q - \left[\left[D_1 \right] \right]_q \right) \\ &= \sum_{x \in \xi_{\mathbb{P}^{\times}}^{\times}} \omega^x \left(\left[\left[D_2 \right] \right]_q - \left[\left[D_2 \right] \right]_q \right) \quad (177) \end{aligned}$$

where $\xi\mathbb{F}_p^\times$ denotes the nonzero elements of $\xi\mathbb{F}_p$. Recall that the semantics $\llbracket - \rrbracket_q$ is a matrix with entries in $\mathbb{N}$, so the above is a linear combination of the $\{\omega^x\}_{x \in \xi\mathbb{F}_p^\times}$ with coefficients in $\mathbb{Z}$. Since $\{\omega^x\}_{x \in \xi\mathbb{F}_p^\times}$ are linearly independent over $\mathbb{Z}$, we have that for all $x \in \xi\mathbb{F}_p^\times$,

$$\left[\left[D_1 \right] \text{---} \bigcirc_x \right]_q - \left[\left[D_1 \right] \text{---} \bigcirc \right]_q = \left[\left[D_2 \right] \text{---} \bigcirc_x \right]_q - \left[\left[D_2 \right] \text{---} \bigcirc \right]_q \quad (178)$$

But note that the above holds trivially for $x = 0$. So moving terms around, we have that for all $x \in \xi \mathbb{F}_p$,

$$\left[\left[D_1 \right] \text{---} \bigcirc_x \right]_q + \left[\left[D_2 \right] \text{---} \bigcirc \right]_q = \left[\left[D_2 \right] \text{---} \bigcirc_x \right]_q + \left[\left[D_1 \right] \text{---} \bigcirc \right]_q \quad (179)$$

This allows us to open up the wire and obtain

$$\left[\left[D_1 \right] \right]_q + \left[\left[C_1 \right] \right]_q = \left[\left[D_2 \right] \right]_q + \left[\left[C_2 \right] \right]_q \quad (180)$$

where $C_1 - := D_2$ and $C_2 - := D_1$. (181)

Lemma 9.3. *Let $\tilde{Z}$ be the following diagram in $\mathbb{L}_{\text{Span}_q}$:*

$$\text{---} \boxed{\tilde{Z}} \text{---} := \text{---} \langle 1-x^{q-1} \rangle \text{---} \text{---} \quad (55)$$

Then the following rewrites hold in $\mathbb{L}_{\text{Span}_q}$:

$$\text{---} \boxed{\tilde{Z}} \text{---} = \text{---} \quad \text{---} \boxed{\tilde{Z}} \text{---} = \text{---} \quad (56)$$

meaning that $\tilde{Z}$ serves as a controlled version of $\bigcirc$ —; and moreover the following rewrite holds in $\mathbb{I}_{\text{Span}_q}^{\text{Fourier}}$:

$$\text{---} \boxed{\tilde{Z}} \text{---} \textcircled{1} = \text{---} \bullet \quad (57)$$

PROOF. Equation (56) follows from the completeness of $\mathbb{L}_{\text{Span}_q}$. For equation (57), we have

where the last equality follows from the completeness of $\mathbb{L}_{\text{Span}_q}$. $\square$

Lemma 9.4. *For any state $\boxed{\Psi} = \bullet \text{---} \overleftarrow{g} \text{---} \overrightarrow{f}$ in $\mathbb{L}_{\text{Span}_q}$, there is a diagram $1 \text{---} \boxed{\tilde{\Psi}} \text{---} n$ (the so-called controlled state of ψ) such that the following are rewriteable in $\mathbb{L}_{\text{Span}_q}$:*

$$\text{---}\bigcirc\text{---}\boxed{\tilde{\Psi}}\text{---} = \text{---}\bigcirc\text{---} \quad ; \quad \text{---}\bigcirc\text{---}\boxed{\tilde{\Psi}}\text{---} = \boxed{\Psi}\text{---} \quad (59)$$

Explicitly, $\tilde{\psi}$ is constructed as

$$1 \text{ --- } \boxed{\tilde{\Psi}} \text{ --- } n \quad := \quad \text{[Diagram of a box with } \tilde{\Psi} \text{ and internal nodes]} \quad (60)$$

PROOF. First, we verify by plugging in $|0\rangle$:

Next, we verify by plugging in $|1\rangle$:

Lemma F.1.

$$\left[\begin{array}{c} \text{---} \\ | \end{array} \right] = |01\rangle + |10\rangle \quad (182)$$

PROOF. We will omit the semantics brackets $\llbracket - \rrbracket_{\text{ZH}}$ for the rest of this proof, for readability.

$$\begin{aligned}
 & \text{Diagram 1} = \sum_{x,y \in \mathbb{F}_q} \text{Diagram 2} \\
 &= \sum_{x,y \in \mathbb{F}_q} \delta_{x+y,1} \text{Diagram 3} = \sum_{x,y \in \mathbb{F}_q} \delta_{x+y,1} \text{Diagram 4} \\
 &= \sum_{x,y \in \mathbb{F}_q} \delta_{x+y,1} \delta_{y^2,y} \text{Diagram 5} = \begin{bmatrix} |0\rangle \\ |1\rangle \end{bmatrix} + \begin{bmatrix} |1\rangle \\ |0\rangle \end{bmatrix}
 \end{aligned}$$

Proposition 9.5. For any states $\boxed{\psi} \vdash n$, $\boxed{\Phi} \vdash n$ in $\mathbb{L}_{\text{Span}_q}$, let $\tilde{\psi}, \tilde{\phi}$ be their corresponding controlled states as defined in (60). Then the following diagram has the sum of ψ and ϕ as its semantics:

$$\left[\begin{array}{c} \text{Diagram with } \tilde{\Psi} \text{ and } \tilde{\Phi} \end{array} \right]_q = \left[\boxed{\Psi} \right]_q + \left[\boxed{\Phi} \right]_q \quad (61)$$

PROOF. This follows from the definition of controlled states (Lemma 9.4) and Lemma F.1. $\square$

Proposition 9.6. For diagrams $\boxed{D} \vdash n$, $\boxed{C} \vdash n$ in $\mathbb{L}_{\text{Span}_q}$, letting

$$\boxed{D+C} := \begin{array}{c} \text{Diagram with } \tilde{D}, \tilde{C}, \tilde{Z} \end{array} \quad (63)$$

where $\tilde{D}, \tilde{C}, \tilde{Z}$ are the corresponding controlled diagrams, then the following semantic equality of sums holds:

$$\left[\boxed{D+C} \right]_q = \left[\boxed{D} \right]_q + \left[\boxed{C} \right]_q \quad (64)$$

and moreover, the following rewrite holds in the language $\mathbb{L}_{\text{Span}_q}^{\text{Fourier}}$:

$$\boxed{D+C} \circledast 1 = \boxed{D} \circledast 1 \quad (65)$$

PROOF. Equation (64) follows from Proposition 9.5. Next, we prove equation (65).

$$\begin{array}{c} \text{Diagram 1} \end{array} \stackrel{(\text{Z1-copy})}{=} \begin{array}{c} \text{Diagram 2} \end{array}$$

$$\stackrel{(57)}{=} \begin{array}{c} \text{Diagram 3} \end{array} = \begin{array}{c} \text{Diagram 4} \end{array}$$

$$\stackrel{(59)}{=} \begin{array}{c} \text{Diagram 5} \end{array} = \begin{array}{c} \text{Diagram 6} \end{array}$$

$\square$
